* Before 1890 the exportation from Shanghai did not include Tusseh

* From 1905 the exports from India include Cashmere silks coming by Bombay

* The prices are based upon the Blue Elephant Chop, although quality has deteriorated in the past few years

THE WORLD'S PRODUCTION.

The following figures illustrate the trend of silk production during recent years (*Bulletin des Soies et Soieries 1916*) Production of Raw Silk in 1,000's of kilos

1,000 kilos=27 maunds

* Salonika transferred from Turkey to Greece in 1913

† Export, not production

India is placed as exporting from 1909—1911 an average of 230,000 kilos=506,000 lbs but India produced in those years probably about 1,300,000 lbs of raw silk, of which some 800,000 lbs was used internally.

APPENDIX III.

The following is the letter from the Director of Agriculture, Bengal, proposing the new scheme of using selected rearers in place of completing the scheme for the issue of disease-free seed from nurseries —

From J R Blackwood, Esq, LL B, I C S, Director of Agriculture, Bengal

Calcutta, the 7th January 1916.

I have the honour now to reply to Government letter No 657-R of the 13th May 1913, in which I was requested to work out a complete scheme for eliminating disease from the Bengal silk-worm. To accomplish this, it is proposed to rear all the seed necessary for the province under the supervision of Government officers. In other words, every moth will be subjected to microscopic examination before its eggs are used. With a view to this object, I pointed out that, in order to estimate the amount of seed necessary for the whole province, it was necessary to find out the area under mulberry in the Province. A census of mulberry lands has accordingly been taken of the four districts of Malda, Murshidabad, Rajshahi, and Birbhum and the area has been found to be 18,547 acres. In the rearing districts of Midnapur, Hooghly, Burdwan, Nadia and Bogra, the area is 650 acres. The total area for the province is therefore 19,197 acres. The amount of seed necessary for the province is obtained by the following calculation. From each acre of mulberry 360 kahans of cocoons can be reared. The total annual outturn of cocoons can therefore be put down at 6,910,920 kahans. The quantity of seed needed to supply this amount is one hundredth part of the total, or 69,110 kahans.

2 It is calculated that a central nursery will not be able to supply more than 3,000 kahans of seed cocoons per annum. Supposing it were decided therefore that the entire seed necessary for the whole province should be supplied by Government, 22 central nurseries would be required for the purpose. Since my letter of the 19th June 1912, I have discovered, however, that in France, Italy, Japan and China, Government in no case attempts to supply the entire seed required. The principal quantity is supplied through professional rearers working under Government supervision. Further, it is most important that the existing professional silk-worm rearers should not be ruined by the action of Government. This would be what would happen, if the scheme as originally conceived were carried into effect. I therefore do not propose to open any new nurseries. The new nurseries in Bogra and Malda which we have recently opened were absolutely necessary for reasons other than the mere supply of seed. The Bogra nursery is absolutely necessary for supplying chotapoli seed to the other nurseries, and the Malda nurseries are necessary for the exchange of nistari seed. I have already reported that the system which was in vogue previous to the opening of these nurseries of depending for seed supply on village seed was most unsatisfactory and a very great improvement has been effected by the introduction of the system of interchange of seed between nurseries.

3 We have at present 7 nurseries (excluding Bogra) and I propose to rear about 10,000 kahans of seed cocoons from each nursery with the aid of professional rearers under Government supervision. This means that the Superintendent of each nursery will have to see that about 75 kahans of seed cocoons are given to selected professional rearers for the purpose of selling the next generation for seed only and not for filatures. Each nursery therefore through professional rearers will thus produce about 7,500 kahans annually.

4 It is proposed that the seed reared in the houses of professional rearers should be subjected to the same supervision as that reared in the nurseries. In other words each moth will be examined by the Pasteur system. It is calculated that a selected rearer will be able on the average to rear seed cocoons from 3 kahans of nursery seed and a supervisor will be able to control from

IV —Cost for each Central Nursery to disinfect the houses of professional rearers and supervise the rearing of 7,500 kahans of seed

Name of district	Name of Nursery.	Cost	REMARKS
Murshidabad	Berhampur	Rs. 1,000*	To rear 7,500 kahans of seed cocoons by selected professional rearers under the continual supervision of an Assistant Farm Superintendent and seven Supervisors and under the occasional supervision of the Farm Superintendent, 25 rearers may be selected to rear seed for each nursery, of which granting even although 5 men fail to rear seed for such reasons as accidental fire, storm, from want of mulberry or flood, etc., as usual, 20 rearers will be able to raise the 7,500 kahans. The cost for disinfecting 25 rearing houses during four crops in a year and supplying wire netting and thread nets would be at least per year Rs 1,000
	Kumarpur	1,000	
	Chandanpur	1,000	
Malda	Piasbari	1,000	The expenditure on Bogra will be incurred for 40 rearers annually for each village rearing house at Rs 4-8 0 each. The other nurseries will be supplied with chotapoli seed by the Bogra nursery. The remainder required by the public will be supplied by professional rearers
	Amriti	1,000	
Rajahmundry	Mirganj	1,000	
Birbhum	Kalitha	1,000	
Bogra	Bogra	180	
	TOTAL	7,180	

* Composed as follows —

(1) Thread nets Rs 500

(2) Copper sulphate and sulphur and wire nets Rs 500

PROVISIONAL STATEMENT BY MR MAXWELL-LEFROY FOR THE BENGAL SILK
COMMITTEE MEETING, JANUARY 10TH, 1916

1 The position at the end of 1915 is as follows --

(1) Nurseries exist at 7 localities, having a total of 32 rearing houses, and 356 bighas of cultivated mulberry, in 1914-15, these issued 8,142 (produced 10,500) kahans of cocoons, capable of producing 16,000 maunds of green cocoons, there are 19,147 acres of land under mulberry cultivation, giving about 100,000 maunds of green cocoons, therefore the present nurseries now supply some 16 per cent of the seed required. The nurseries are now short by 17 of their full number of houses, with 49 houses, it is estimated by the Silk Superintendent that 24,000 kahans should be produced, *i.e.*, there should now be 15,700 kahans produced, on the existing houses, on the existing acreage, 356 bighas should give a big bund of 5,696 maunds of leaf, or 19,936 maunds in all in the year. These should yield 11,392 kahans in one bund or 39,872 in all. But 32 rearing houses each with 8 ghoras of worms will not produce one bund of more than 7,680 kahans or 28,160 in all in the year. It appears as if there is a great difference between the actual output and that theoretically possible on the basis of mulberry available or rearing houses available.

At the same time, supposing the houses were fully occupied and the full yield obtained, the possible output from the area of land is as much as would be absorbed now and about half that required for the whole area. Ghose estimates that 69,000 kahans are required for all Bengal. Lalont estimated that a big bund supply of 30,000 kahans and a total of 100,000 for the whole year would be needed. It looks as if better production on the existing nurseries would do a large part of this. The provision of 17 more rearing houses would produce another 4,080 kahans in the big bund or 14,960 more in all in the year. Which would be 11,760 in one bund, or 43,120 in all, allowing 20 per cent for accidents, rejections, etc., deduct 8,600 kahans, giving 34,500 kahans, which is just 50 per cent of the required total.

The cost of 17 more houses would be over Rs 42,000 at Rs 2,500 each (Blackwood's Estimate is Buildings 74,360, Land 9,940 and Cultivation 14,050. Total 98,350, this includes overseers' quarters) and there would be the extra labour, mostly of the cheaper kind.

(2) *Selected rearers* — The number varies, but it is now 29 and would be in all about 35 to 40, assuming each supervisor (10) to look after 4 selected rearers. Each can turn out 120 kahans seed at a bund, say 360 kahans in all, a total of 10,440 now or 14,400 eventually. The cost of the supervision in all is Rs 250 per month, or Rs 3,000 a year, and there is the cost of the wire gauze, disinfecting, etc. At the present time the selected rearers could not produce more than 16 per cent of the required amount.

(3) The nurseries now produce 10,500 and issue 8,000 kahans, and when fully worked according to the Silk Superintendent should turn out 24,000. There remains 45,000 kahans to be got if the nurseries are completed and work at the Superintendent's estimate or 54,000 if they are not.

It will require then another 83 selected rearers if the nurseries are completed or 111 if they are not, entailing a further 21 or 28 overseers accordingly.

(4) The estimates of the total cost of the nurseries, required to produce 69,000 kahans of seed cocoons, or of nurseries *plus* selected rearers are apparently difficult to prepare, the estimates of the original nurseries, the revised estimate of the Director of Agriculture in 1915, the amended estimate of 1915 vary very much. The original in 1912 was a capital cost of 3,48,000, the revised in 1915, a capital cost of 8,21,964. The amended of 1915, a capital cost of Rs 3,03,000, allowing for what has been done between 1914 and 1915. I assume the enormous total of 1915 to be based on the present outturn of the nurseries and I consider the present outturn to be very small indeed whereas previous estimates were based on possible outturn.

If the fine cultivation, the pure seed, the good rearing of the nurseries can only produce 8,142 kahans of seed cocoons from 32 houses with 356 bighas of land, then it does not seem likely that any scheme of nurseries will do

much. But I am very strongly of opinion that the nurseries are not being worked to anything like their capacity.

(5) The comparative value of the nursery system and the selected rearer system cannot as yet be estimated, but it is clear that there is an enormous element of risk in the latter system which is absent in the first. The temptation to a selected rearer, able to sell his seed cocoons sometimes at Rs 1/12, Rs 2 a kahan, to make 1 maund into $1\frac{1}{2}$ maunds by adding ripe worms ready to spin from a brother's house, is enormous, and to prevent it a supervisor is employed, such a system is doomed to failure unless the supervision is very close and continuous, and the difficulties of ensuring its effectiveness once it becomes a matter of routine will be enormous.

The control over the seed from the nurseries is much greater, the staff are paid salaries and not by results, they have no inducement to bring in and mix inferior stock even if they can do so and the chances of infection occurring in the stock are very much smaller. The rearers stock, however good to start with, has a long period in which to get infected and the risks are considerable, yet that stock goes out as Government seed. The best policy under present circumstances would seem to be—

- (1) Increase the output from the nurseries very much. They should work at the maximum of output. I have the impression that they do a little very well, but they could do much more. There is a great waste of accommodation in the houses in the fly-rooms which might well be rearing rooms with verandah fly rooms, the available leaf is not fully used, the ghoras are not fully used and I would ask if greater output could not be secured.
- (2) Use the available selected rearers, supervising them as closely as possible and estimate from this experience the value of the scheme. Every supervisor should have the full number to look after.
- (3) Appoint no more supervisors but expand, if that is possible, on the nursery staff and increased nursery seed.
- (4) As soon as possible, extend the nurseries by erecting the remaining rearing houses and bringing into cultivation all the possible land.

Staff—The Committee that met in 1908, recommended a Superintendent of European birth, with A. C. Ghose as Deputy Superintendent. This has never been carried out, and to this must be attributed the present position.

A. C. Ghosh is an energetic man, devoted to the issue of disease-free seed, he does this extremely well and the success of this is due to his energy and carefulness. But he is not able to do more, his view is limited to that one point and to securing that, he is unable to work well with others of equal or greater ability, he has fixed ideas on the question of hybrids, etc., and he is not able to energetically pursue a wide policy.

In this I see the key to the whole position and seeing that the Committee are retaining Grangeon on half pay, his appointment as Deputy Director is indicated, whether he can be got back from France during the war is doubtful, but his return can be prepared for by pressing the policy with regard to hybrids that has been indicated above. The first and most vital thing is to pursue a more active policy, not necessarily spending large sums of money but tackling the whole problem on wider lines and more energetically. Whether this will be done by a European or an Indian is immaterial, but success depends upon it. At the present rate of progress the industry will not recover. The Silk Committee have only a limited power, they advise mainly, the Director cannot devote more time to the question and it turns entirely on the permanent head of the sericultural staff.

2 HYBRIDS AND UNIVOLTINE RACES

There are available the following races —

Italian or French, univoltine

Italian-Japanese, univoltine

Boro-polo, univoltine
 Chota-polo, Multivoltine
 Nistari, Multivoltine
 Mysore, Multivoltine
 Madagascar, Multivoltine from univoltine stock
 Cleghorn's, Multivoltine from univoltine stock
 Madagascar by Multivoltine hybrids
 Nistari-Univoltine hybrids
 Mysore Univoltine hybrids
 Univoltine-Multivoltine Mongrels

These are being investigated for—

- (1) Voltine character
- (2) Color
- (3) Cocoon weight
- (4) Character of silk

The investigations come mainly under four centres

Miss Cleghorn
 Berhampur, Chondhery
 Berhampur, A. C. Ghose
 Pusa, M. N. De

(This is dealt with fully under Hybridisation in Chapter X of Volume I.)

It is necessary at the outset to distinguish two very distinct problems, one the improvement of the existing nistari and chota-polo, the other the substitution of a better yielding race, producing a different quality of cocoon.

For the first there are three distinct problems —

- (1) The production of a multivoltine hybrid, so like nistari or chota-polo that rears will take it and get better yields. This must be multivoltine to the extent of at least 80 per cent, the worms must not be zebias or banded, they must not be too large, they must feed on bush mulberry.

By far the most hopeful at present is Miss Cleghorn's race, but all the experiments made so far, by all workers, have been on so small a scale that no information is available as to 'outturn'. You may get individual cocoons of greater silk content, but till these have been produced on an industrial scale, from at least a few kahans of seed, we cannot really form any opinion as to their merits.

It is extremely important that this should be done soon, and if it could be done this year before October, the results would be available for recommendations to be made.

I am averse to removing any race from the control of its producer till it is tested on a larger scale, and I do not advise taking Miss Cleghorn's away from her control, but she should have the necessary facilities for extending her cultivation and rearing proper broods.

At Berhampur, the best race can be easily grown on a larger scale, and I have suggested this for the Pusa race.

- (2) Selection from pure strains of nistari and chota-polo

This can be done and is being done constantly and unless selection is going to be done on some new character, *e.g.*, a round-ended cocoon, I see little hope in it. But it could be done without much difficulty.

- (3) Improvement by hill cultivation. Seeing that the biggest *bund* is the November one, it seems likely that seed from worms grown in the hills during the rains will give better cocoons, whether this can be done at Kurseong at all, or whether some other

station would not do better, is doubtful, it is at all events not feasible immediately, but I attach great weight to the formation of a proper hill nursery at a low elevation in a place where the rainfall is not too excessive

The substitution of a better race of worms altogether is a problem which presents distinct difficulties

The raw silk produced will be different, will find a separate demand, will be used for distinct purposes. It would be possible now to issue Mysore seed, or univoltine seed, and to get cocoons produced, but if that was done through the existing organisation, it might seriously prejudice the efforts to produce pure seed of existing kinds. It is of no advantage to one rearer to get a crop of nice univoltine cocoons yielding white silk, and requiring only 9 kahans to the seer. There is no market for small lots, the market for large lots has to be found and the silk would be an inferior quality, competing with better qualities of the same kinds. If by any race, it were possible to produce exactly the quality of silk that is used in India as China silk and if this were produced and sold in Indian centres, then a profitable extra brood would be added, but to introduce this will require tact, care and organisation. Were there a European officer in charge, who could leave to the Deputy Superintendent the seed-issue and who could energetically pursue a wider policy, I believe he would be successful in this particular policy.

At the present time it is impossible, the officer is not available and the present seed-issue would be prejudiced if the staff had this to do as well.

3. DISEASE

Pebrine, grasserie, flacherie, muscardine still exist and are factors in the situation. The first, in spite of nurseries and examination of moths, persists in the nurseries and about 5 per cent of the moths still have it. There can be no doubt that a careful investigation of pebrine and other diseases would pay, if it were done by a first-rate man. There is no definite information for India as to the length of time the organism remains alive, the best process of disinfection, the treatment of earth floors or thatch roofs, European practice is followed, and this does not necessarily apply to Bengal conditions.

4 THE PLANT

In the nurseries, bush mulberry is grown, of two kinds, the *deshi* and the "Bombay". I am informed that the latter is an European variety grown as a bush, that it is better than *deshi*, and that it is being planted in the nurseries.

Miss Cleghorn has a mulberry which produces no fruit, only male flowers, of which the leaf is said to last longer and suit the hybrids better. At Ramnugger, the "Bombay" plant is grown as a dwarf standard, from a single stem, at Pusa the *deshi* as a 4-foot standard on a single stem from the bush, the bush yields most per acre say 300 maunds, the standards yield less, say 240 maunds, but of better quality.

These points should be settled definitely and the question of the plant taken into account. If the best plant is a "Bombay" plant grown as a standard, then efforts might be made to get this more generally adopted.

5 THE FUTURE

If there were a competent Superintendent, completed nurseries, bigger output, a hill nursery, industrial hybrids or ameliorated races, would the industry revive? there are three points in this—

- (1) To some extent the failure is due to the increasing cultivation of other equally profitable crops where that is the case, there is no reason to interfere.
- (2) Where the industry is still going on and where no substitute exists, there are many who would benefit by pure seed, by full crops, by better crops. Those who rear little would rear more. Many who

have given it up would return and prosperity would replace depression. Nothing is more astonishing than the enormously increased output of Bengal silk when the East Indian Company improved the reeling, when the East Indian Company benefitted by a tariff at home and the cutting off of European silk, and when in the sixties pebrine enormously reduced the European output, from these I argue that a very much larger output is possible, will come about and will greatly benefit the reapers.

(3) If this occurs, will the output be absorbed?

There are two factors here, the export from India, and the consumption in India.

For the first, increased output means increased use, a limitation in supply means that manufacturers accustomed to Bengal silks go to other qualities because it is essential that they must get a steady supply, were the supply to multiply ten-fold, the silk would be used on a larger scale, the manufacturer being sure of his supply, where the limit of absorption would be, cannot be decided, but there is ample room for expansion. For internal use, there is a limit under present conditions to the use of the poorer qualities, at present the coarser silks are absorbed, and there is no impetus to reel better, but if the whole demand for coarse silks were satisfied, the reelers would readily produce the qualities for export or that the mills would absorb if they could get a large and steady supply. I have ascertained this from direct enquiry in the weaving mills and I believe that in this also, increased output means increased demand *at the same price*. It is unlikely that the relative price of Bengals and Italians will alter, but the more Bengals produced the more will be absorbed at the same relative price up to a certain point.

The factor of fixity of price must be realised clearly and there is a perfectly definite ratio between the value of Bengal silk as compared with others, whatever the supply. If absence of disease, better mulberry, better yields will increase the outturn of raw silk, then this will be absorbed at the same relative price and the maximum possible outturn of the areas in which it pays to produce silk, for that price, will probably not be near the amount that will be absorbed.

If better qualities are produced, then every pound produced in Bengal would probably be absorbed at a price much higher than that of the present quality.

There is at present every reason to believe that we are justified in doing all that is possible to revive the industry in districts where no more profitable one has replaced it, and it is probable that a good deal can be done successfully to increase the outturn and the value.

APPENDIX TO NOTE

The following is the expenditure incurred on the nurseries and the amount realised by the sale of cocoons.

	Recurring			Non-recurring			Cocoons sold			Cocoons bought		
	Rs	A	P	Rs	A	P	Rs	A	P	Rs	A	P
1910-11 . .	14,527	14	4	7,114	7	0	6,649	10	6	51	0	0
1911-12 .	21,306	0	3	5,912	15	9	6,831	12	6	97	15	3
1912-13	30,960	9	5	8,621	0	0	6,025	10	3	21	8	0
1913-14	51,585	14	4	46,004	5	7	4,982	8	9	183	0	0
1914-15 .	65,713	1	9	49,535	4	6	10,889	4	0	14	0	0

In 1914-15, there were produced 10,500 kahans of seed cocoons of which 8,142 were sold, capable of producing some 16 per cent of the requirements of the area of mulberry. The capital and recurring expenditure needed to secure this is high and the return from an expenditure in 1914-15 of over one lakh of rupees is distinctly small.

APPENDIX IV.

The reports reproduced deal with the question of the economic condition of the rearers affected by the decline of the industry. The first is a letter from the Collector of Murshidabad written in 1912

From R C Hamilton, Esq, I C S, Collector of Murshidabad

Berhampur, October 1912

It is necessary to consider the interest (a) of rearers, (b) of the "skilled artisans" as they may be called who work in filatures, (c) of Indian filature owners, and (d) of mulberry growers

(a) It is a well-known fact that the rearers in the course of a few generations have acquired great practical knowledge and skill as to the best methods of rearing silkworms

The principle that "there is very little that we can teach the cultivator" applies also to rearers, and it would be a great pity, merely for this one accident of spread of disease among silkworms, which by the monopoly proposed, is preventable, to allow all such inherited and acquired skill to go to waste

(b) It is a further well-known fact that the workers in filatures are a special skilled class of their own. Having acquired within doors sheltered from the sun the delicate touch necessary for handling silk, these people (mostly poor low caste Hindus), have become unsuited for other or for outdoor work and for the hard work of agriculture. The distress into which these comparatively delicately natured artisans have fallen and, unless the industry is saved, will continue to fall, is very acute, and though they are unable to attract Government's attention to their distress, it is none the less very widespread. They are unable to take to agriculture and other employments. For the same reasons as apply to the "rearers" it will be a pity to allow such skill to go to waste

(c) The views of Indian filature owners are contained in the 1906 report. They apply with still more force now-a-days

The opinion of such Indian filature owners was so emphatic that disease had caused the industry to die out, that I wonder nothing more was done than to check the disease

(d) *Mulberry growers*—Like the rearers and the workers in filatures, the mulberry growers have acquired considerable skill and knowledge as to the best method of growing mulberry plants. We cannot teach them much in that respect, yet, for want of a market for the leaves, they are gradually giving up growing mulberry plants and their skill is going to waste

Extract from the Imperial Gazetteer of India, Bengal (Midnapore District)

Midnapore is a heavy criminal district, and has long been notorious for the number of dacoities committed within its borders. These are largely the work of Tuntias, a Mohammadan caste, whose traditional occupation is the cultivation of the mulberry-tree (tunt) for feeding silkworms. This occupation having become unprofitable, many of them have taken to criminal courses, and are professional thieves and dacoits

(The Bogra Gazetteer has the same remark)

Direct enquiry has been made also from the district officers of the four districts, Berhampur (Murshidabad), Malda, Rajshahi and Birbhum, their reports are as follows —

From L S S O'Malley, Esq, I C S, Collector of Rajshahi

Dated the 26th January 1916

In this district the decline in the silk industry has led to the silk rearers and reelers taking to other occupations. Most of the expert reelers who used to work in filatures now earn their livelihood as labourers, and the great majority of the cocoon rearers are now cultivating jute and other crops. The latter had already land on which they grew mulberry and for which they paid a high rent, and when cocoon rearing ceased to pay, they substituted other crops for mulberry. So far from their abandonment of their old cultivation being the cause of the downfall of the industry (as has been suggested in the letter of the Imperial Silk Specialist), it is a direct result of its decline. It cannot be said that the substitution of other occupations has led to distress in this district.

From the District Officer of Birbhum

Dated the 16th February 1916

It appears from enquiries made that there has been a considerable diminution in the production and in the earnings of men who rear silk worms and reel cocoons. No satisfactory explanation, however, could be obtained except that the quality of the seed generally used by the rearers of silk worms is bad.

2 It also appears that the rearing of silkworms is not so paying now as it used to be. In view, however, of the large demand for silk, the reason for this can only be either foreign competition or circumstances affecting the yield. The defective quality of the seeds may be one of the causes which have reduced the yield.

3 Rearing of silkworms or reeling of cocoons is practised as an additional source of income in this district by the cultivators along with agriculture. It is seldom practised exclusively.

4 There was a silk factory in this district at Ganutia in thana Labpur under European management. This factory has been closed some years ago. When the factory worked the rearing and reeling of cocoons and cultivation of mulberry plants were both profitable to the people of the village and its vicinity. The majority of the labourers, who found employment in the factory, have left their homes since the winding up of the factory in search of work elsewhere and those that remain in the village are in distress. Rearing of cocoons and cultivation of mulberry were additional sources of income to cultivators and as they have now got to depend entirely on agriculture they have become poorer. The income in the value of agricultural produce has not compensated the loss they have incurred through the diminution of the industry.

5 It does not appear, however, that there has been any appreciable increase in crimes on account of the closing of the factory or the diminution of the silk industry generally.

From T Johnston, Esq, Collector of Malda

Dated the 19th February 1916.

There is no doubt that there has been diminution in the production of silk which may be ascribed to the following causes —

(1) Want of good seed

- (2) Diseases of silkworms known as *Kalsira*, *Rosha Boka*, *Lalmatha* are now more common
- (3) Less demand for Bengal silk in Foreign countries and less export in consequence—
 - (a) on account of war,
 - (b) on account of market being taken up by Japanese silk, China silk and other varieties of cheap silk
- (4) Withdrawal of European capital and abolition of silk factories in Bengal
- (5) Ignorance of people in scientific methods of rearing and reeling and their consequent failure to compete with foreigners
- (6) Rise in the wages of labour

2 It is true that the silk industry has declined to a considerable extent and that some people who used to rear silkworms or reel cocoons before, have taken to agricultural or other means of living. But this is a result of the diminution in the industry of sericulture rather than its cause. It appears, however, that in this district sericulture is practised with very few exceptions not as an independent profession by itself, but as one to supplement the income from agriculture. The diminution in outturn and the falling off in the prices of silk might have caused some people to adopt other means of living, but I do not think that this has led to any serious distress. Rise in the value of agricultural produce does not seem to have induced people concerned with sericulture to adopt the former in preference to the latter.

From W D R Prentice, Esq, I C S, Collector of Murshidabad

Dated the 29th February 1916

I asked three of the European silk employes in this district for their views on the points raised in Mr Maxwell Lefroy's letter and also had enquiries made among Indian silk dealers in this neighbourhood, but regret to state that the information supplied after a good deal of delay is of very little value.

2 I gather, however, that the diminution in the earnings of those engaged in the different branches of the silk industry has caused a certain amount of distress, especially among reelers. The women, it is stated, have been more affected than the men, which is not surprising, as the latter can easily earn money elsewhere as labourers. There has, however, been no noticeable increase in crime as the result of this. This indicates that those affected have found some other means of livelihood.

3 The main cause of the decline of the industry is stated to be the importation of cheap silk from abroad and not the increase in the value of agricultural produce, though in some cases this may have taken a factor of secondary importance.

APPENDIX V.

The following papers illustrate the history and present position of Kashmir —

Extract from Duseigneur Kleber, Le Cocon de Soie (1875.)

CACHEMIRE

En avril 1860, MM Orío et Consonno, graineurs italiens, s'embarquent pour l'Inde. Ils arrivent en mai à Calcutta, où, aidés des bons offices du gouvernement anglais, ils peuvent se diriger vers le royaume de Cachemire et procéder à un grainage assez important, 25,000 onces. Ces semences sont emballées dans des caisses entourées d'une épaisse couche de laine et aérées seulement la nuit, elles arrivent en très-bon état en Italie, fin Novembre.

Soumises à l'examen microscopique de MM Vittadini et Cornalia, ces observateurs les déclarent saines en tous points.

Le Cachemire doit être, pour la température, assimilé aux régions froides de l'Italie, l'incubation s'y fait seulement dans les premiers jours de mai.

La feuille est fournie entière au ver dès le premier âge, non détachée des rameaux, une fois par jour seulement jusqu'au troisième, et l'éducation se continue ainsi à la méthode turque, mais avec une alimentation mesquine. Elle dure quarante jours, et le ver file son cocon sur l'édifice d'un mètre de haut, constitué par les rameaux entassés.

Le cocon Cachemire (figure 179) a la plus grande analogie de forme et de grosseur avec les races d'Albanie et Montenegro, mais il est loin d'avoir leur solidité de coque.

Il a fallu au fileur généralement 16 à 18 kil de cocons pour un de soie.

L'on a dit, à l'époque, le maharadj s'opposait à une nouvelle expédition de graineurs dans ses États. Je crois que l'obstacle vrai est dans l'insuccès de la première.

CACHEMIRE

Cocons de graine docteur Orío

Format ovale, allongé, moyen

Un bout en pointe

Grain fin

Coque faible

Blanc et jaune ordinaire

Diamètres 340-170 mm.

Deciusage 23—25 pour cent

Frisons 30—32 pour cent

Cocons doubles

Rente 16—18.

Peu de duvet

Extract from Sir Walter Lawrence's 'Valley of Kashmir.'

The history of sericulture in Kashmir has been fitful and desultory. The silk industry is of ancient standing, for Mirza Haidar in his history (A.D. 1536), alludes to the abundance of mulberry trees in Kashmir, and to the fact that the people would not allow the leaves to be used for any purpose other than that of food for silk worms. It is said by the people that sericulture existed in the times of King Zain-ul-Ab-din, that it had fallen into disuse in the Pathan times, and that the Pathans restored the industry. In later times the important date is the year 1869, when Maharaja Ranbir Singh,

an enthusiast in new industries, revived the silk production on a large scale. No expense was spared, and 127 fine rearing houses were built in all parts of the Valley. Reeling appliances and machinery were imported from Europe, and a large Department was formed for the purpose of developing a business in silk. It is easy to be wise after the event, but the idea suggests itself that the system of revival was not wise. A guild of silk rears known as *Karm Kask* (literally worm killers) was created, and these men were given certain privileges, such as exemption from forced labour. They were also allowed to annex the houses of villagers for silk-breeding purposes, and they were further appointed as informers regarding damage done to mulberry trees. In a short time the name *Karm Kask* became hateful to the villagers, and there is no doubt that the silk rears abused their position and oppressed the people. The whole business was too official, and the general public looked upon it with hatred or disgust. Next it may be said that the revival was too ambitious. The cost of buildings and plant was enormous, and the rearing-houses being scattered in all parts of the Valley could not be properly supervised. Unfortunately there was no one possessing any technical knowledge to supervise, and though great improvements were made in reeling there was no man in Kashmir who could avert the calamity, which befell the industry in 1878, when nearly the whole of the silk worms were carried off by disease. Every credit is due to Babu Nilamber Mukerji, the Chief Justice of Kashmir, for his effort, and his success in improving the reeling of silk is attested by the favourable reports received from Europe, all speaking highly of the quality of the fibre. The industry lingered on until 1882, and from that time to 1890, the State left it to the silk rears. The quantity of seed rapidly diminished, and sericulture was virtually at an end. The fine buildings had fallen down and out of the 127 houses built in 1869, only two remain, one at Raghnathpura and the other at Chitpuri. It is generally understood that the disease which proved so fatal was brought into Kashmir with the imported seeds of highly domesticated, though superior, foreign cocoons, from Europe, China and Japan. The rears declare that the Japan seeds were the cause of the calamity. In 1889, on the advice of Sir Edward Buck, C.S.I., Secretary to the Government of India, it was decided to follow the example set by Bengal, and to adopt the Eastern system of microscopical examination. The services of a trained Bengali were obtained, and a Kashmiri was deputed to Bengal to learn the system of microscopical examination. Good seed was imported from Italy and France, and an excellent crop of cocoons was obtained. In 1891, the success achieved was nullified by the neglect of the subordinates, who were unfortunately left in charge at a critical time, and progress was temporarily arrested. The operations from 1889 to the beginning of 1894 were under the charge of Babu Rishbar Mukerji, the Chief Justice of Kashmir, a brother of Babu Nilamber Mukerji. Though I was associated with him in the work, he deserves all the credit for having achieved the chief object of securing healthy local seed. This year, 1894, while imported seeds have in many cases bred diseased worms, the worms from our examined seeds have done splendidly, and there is no disease among them. Owing to financial reasons, at the beginning of 1894, Babu Rishbar Mukerji's connection with sericulture terminated, and I was placed in charge. My object since I was associated with sericulture in 1889, has been to avoid expense and to limit our efforts to obtaining healthy seed. Knowing that the Kotahar Valley contained a number of old silk-rears, I have this year given all our seed to the Kotahar people. Supervision is thus rendered possible. I have further raised the price paid by the State for cocoons so as to give some profit to the rears. Our expenditure has been covered by our income, and unless some unforeseen calamity occurs, we shall have seed sufficient to supply all the old silk-rears in 1895.

* * * * *

Everywhere I find the villagers eager to take up sericulture as a cottage industry and from all parts of the Valley, men have this year implored me to give them seed.

* * * * *

It is impossible to exaggerate the potentialities of silk in Kashmir, but I am certain that these potentialities will never be realised while the industry remains in the hands of the State

REPORT OF THE KASHMIR SERICULTURE DEPARTMENT FOR SAMBAT 1972 (1915-16)

It is gratifying to note that in spite of all the difficulties which the Department has had to face the year under report has been more prosperous than any one expected it to be, and the prices realized reached a record height. For the first three months of the year, the market was quiet with prices ruling just about at the same low level to which they had fallen at the end of 1914. In July, however, a marked change became apparent. It was realized that silk was required for a multitude of articles which could not be in any way regarded as luxuries and there was no general falling off in the demand for silk as prophesied by the pessimists. Moreover, cocoon crops had been decreased all round and simultaneously America was enjoying unbounded prosperity and was easily capable of absorbing more than all the remaining silk which was not wanted by Europe.

The sudden revival of the silk market and the rapid advance in prices both for silk and cocoons may specially be attributed to the following reasons

- (a) Shortage of the European crops
- (b) Heavy purchases by America
- (c) The lightness of available stock in Europe during the year
- (d) The persistent rise in Foreign Exchange.
- (e) Stoppage of arrivals from Central Asia.
- (f) Serious floods in Canton destroying one of its crops
- (g) High sea-freightage, insurance and war risks
- (h) Sinking of a steamer with 2,000 bales of silk on board.
- (i) Closure of the Dardanelles
- (j) Stoppage of arrivals to Europe from Syria owing to Turkey being involved in the conflict

It is interesting to note the effect of the war on other silk producing countries and the measures adopted by the various Governments to cope with the situation. The silk industry received a hearty and liberal support in Japan, where, to save it from the effects of the war and in order to afford relief to the people engaged, it was decided to form a Company under the name of the "Imperial Silk Yarn Company" with a capital of about £714,600 of which £510,400 were contributed by the Government. This subsidized Company conducts the purchases and sales of silk with a view to maintaining a standard price for raw silk on the market. It did not end here, but to provide livelihood to the mountain people of the country, on completion of public improvements on which these people were engaged, Silk Culture was introduced in several Provinces. A Mulberry Farm was laid out in the Imperial Palace Grounds to supply leaves to the Imperial Silk Breeding Rooms, where Her Imperial Majesty The Empress of Japan attended to the rearing of silk-worms.

In Bulgaria, the Government encouraged the extension of the mulberry plantation by the gratuitous distribution of seed amongst the land-holders and peasantry. Instructions in the art of silk-worm rearing were given in all Agricultural schools throughout the Kingdom.

In Spain to create an interest in and develop the long decadent silk industry there, the Government formed and sanctioned a legislation which included a Government grant of about £30,000 a year for the support of experimental stations, free distribution of silk-worms' eggs and premiums to sericulturists and spinners of raw silk. In Columbia a law has been made providing for State encouragement of the cultivation of mulberry trees, the

rearing of silkworms and the reeling of silk. A provision has been made for the appropriation of sum of about £2,000 annually from the National Treasury to be distributed amongst the various Departments of Republic and to be used for the foundation and maintenance of schools of Sericulture, the purchase of reeling machines, the payment of premiums to producers of silk and cultivators of mulberry trees. Silk reeling machines imported from abroad have been exempted from import duty for a period of 10 years.

Highest price and offer for Kashmir silk

The highest price which the Kashmir silk fetched (through Messrs Durant Bevan & Co) was 58 francs per kilo and the highest offer which has been accepted, but not realized as yet (through Messrs Cox & Co) was 67 francs per kilo, which at the present high rate of exchange is equivalent to approximately 18s 6d and 21 shillings per pound respectively. This offer of 21 shillings per pound is record for Kashmir.

Demand and sales of silk in India and Siam

The great activity which characterized the silk market in Europe, also resulted in a keen demand which simultaneously sprung up for raw silk in different parts of India and Siam. Orders for different qualities began to pour in, to execute which, I have been compelled to work the three existing old filatures by night as well as day. I much regret to say that owing to the new filatures not being ready I have had in some cases to refuse orders because I was unable to guarantee to supply the goods in the time stipulated.

In last year's report I mentioned that I had every hope of establishing a connection with the Siamese silk market, and I am glad to say that we have been fairly successful in this matter. In the first instance a sample consignment consisting of 400 lbs of No 3 Silk was sent to the firm of Messrs L T Leonowens & Co, Bangkok, who had been recommended to me by Mr Sykes, the Accountant General. This lot only realized about Rs 6-4 per pound net, a very low price but better than Rs 5 which I had been offered in India. A second consignment of 1,335 lbs realized about Rs 7 per pound and a third consignment of 2,667 lbs has been sent for which the firm think they will obtain even a better price.

Some of the same quality as supplied to Siam was also sold in India at prices from Rs 5 to Rs 7 per pound. I hope I shall be able to realize better prices as soon as this quality is better known.

This same quality was also supplied to Messrs Singha & Brothers, who are experimenting with the weaving at the factory. The quality of the cloth appears very good and I understand the firm are having no difficulty in disposing of it in India.

A consignment of 40 bales of No 1 Silk consisting of 4,920 lbs of 9/11 denier and 1,640 lbs of 11/13 denier was sold at the factory at Rs 12-12 and Rs 12-8 per pound net respectively.

Two consignments of 22 and 4 bales of waste chassam were sold for Rs 1-15 per pound for Calcutta, and 24 bales of waste godder were sold for Rs 1-3 per pound for Bombay.

Sales of silk in Europe

569 bales of No 1 silk were sold in Europe at an average price of 12s 8d and the number of bales of waste silk was 123.

Consignment of America

A small sample consignment of 6 bales of No 1 Silk consisting of 900 lbs has been sent to America through Messrs Cox & Co, I am expecting a report on this lot shortly.

Reeling.

The factory reeled silk for 294 days (a record) working 218,233 basins and the average labour employed daily was 1,623. Female labour has been maintained for the sorting of cocoons

One of the chief events of the year was the working of the filatures throughout the winter, which this year was unusually mild. The silk reeled during this period was of a coarse size

I am glad to report that the quality of the Kashmir silk has improved. Our brokers Messrs Durant Bevan & Co, write as follows —

“ The silk we are now receiving shows an immense improvement. Your silk is splendid and we are proud to have the selling of it ”

This speaks for itself but personally I am not altogether satisfied with the quality we are turning out and I hope when the new filatures are at work we shall be able to show a still further improvement and set at rest the doubt as to whether the Reeling Department can be made to pay

Outturn of silk waste

Statement “ B ” will show in detail the outturn of silk and waste during the last three years

Rearing

The rearing operations were again carried on, on the same lines as in the preceding year. We distributed 37,610 ounces of seed which produced 33,860 maunds of cocoons which was not a satisfactory return. I can only attribute this to the following reasons —

- (a) Non-hatchment of a large portion of some of the Italian seed and also one kind of French. These two varieties were delayed in transit from Europe and arrived here rather late
- (b) A certain amount of a local seed started hatching out in the boats whilst in transit from the hibernation rooms to the various distributing centres. The consequence was that some of the small worms, got crushed when being carried by the rearers to their homes or were affected by the sudden drop in temperature which occurred at the time of distribution
- (c) Unfavourable weather, when the worms had reached the fourth moult, frequent dust storms almost every afternoon about 4 P.M.
- (d) Damage done to the cocoons by rats in the rearers' houses on account of unusual delay in the importation of cocoons. This was owing to the outbreak of cholera, when the rearers were prohibited by the medical authorities from bringing their crop to Srinagar

The rearing operations in Skardu were altogether a failure. The quantity of seed distributed was 14 ounces, which only produced 1 maund 24 seers of very inferior cocoons. It has now been decided to discontinue the rearing in this district

The following table will show the result for the last three years —

Year	Number of rearers	Seed issued in ounces	Maundage of cocoons	Produce per oz. of seed	Amount paid to rearers
				Seers	Rs
1970 (1913-14)	47,501	36,735½	37,921½	41	5,61,212
1971 (1914-15)	48,936	36,738½	33,672½	36½	4,92,512
1972 (1915-16)	51,076	37,610	33,862	36	4,95,120

Local seed

The quantity produced was 7,352½ ounces as against 4,400 last year. The accommodation at the silk factory being inadequate as only approximately 4,500 ozs could be produced there so it was found necessary to occupy the Gupkar Distillery as well, which was kindly lent me by the Customs Department as well and 3,182 ounces were produced there and 4,170½ ounces at the silk factory. This seed was distributed this year and the results will be dealt with in the next report.

Finances

The profit and loss sheets will be submitted by the Accountant-General in the due course. The receipts during the year from the sale proceeds of silk and cocoons amounted to over 20 lakhs. (The profit is estimated at 9¼ lakhs, probably more.)

High freightage and shipping difficulties

The steamer freightage, insurance and war risks were extremely high and the shipment of our stock, on account of steamers being requisitioned by the Government of India, was very difficult. In this respect my thanks are due to Messrs Cox & Co., for their co-operation and the keen interest they evinced in making timely arrangements to ship our silk and cocoons and it is due to their foresight and precaution that we have been able to export our output without delay.

Rules and Regulations regarding Protection of Mulberry trees.

1 All cutting of mulberry trees, or branches thereof, is a criminal offence, unless done under the authority of the Inspector of Mulberry Culture.

2 Zamindars are responsible for the mulberry trees, standing in their land. If any one else damages them, the Zamindars should at once report the matter to the Inspector, or to the Lambardar.

3 The Lambardars are similarly responsible for all the mulberry trees in the village, and the Chowkidar is responsible for reporting to the Lambardar all cases of damage to such trees.

4 Holders of previous permits, to cut mulberry trees, were warned on the 10th of May 1962, that all wood held by them, under those permits, should be consumed within six months from that date. mulberry wood afterwards found in possession of any person without the permission of the Inspector, will be deemed to be held in contravention of these Rules.

5 Lopping of mulberry trees for fodder, without proper authority, will be treated as an offence, when it can be proved.

6 The Zamindars are not allowed to use mulberry wood for ploughs, etc. but can obtain other wood for such purposes, from the State Forests.

7 The silt-renters similarly are not allowed to use any mulberry wood for heating of the rearing houses.

8 The sale of mulberry wood, excepting to the Sericulture Department, is absolutely prohibited.

9 All fallen mulberry wood or trees, cut under proper authority, will be collected at suitable places, and disposed of under orders of the Inspector of Mulberry Culture.

10 The rules for the preservation and conservation of mulberry trees, have already been issued in Circular No. 7 sanctioned under Resolution No. 15, dated 24th February 1894, but it appears that the rules are not properly observed. Cases have frequently come to notice, in which officials of the different departments of the State, have cut mulberry trees, and when called for an explanation, have stated that they have done so, as a past practice, and no action was ever taken against them for any such offence. It is considered, therefore, necessary, that all officials may once for all be informed that they are equally with the general public forbidden to cut any mulberry trees contrary to these rules, and it is hereby notified that any person, whether any official or not, who in future infringes these rules, will be liable to punishment, and that the rules will be strictly enforced.

11 If at any time the cutting of the mulberry trees, appears inevitable, for some State purposes, the Inspector of Mulberry Culture, should be previously informed, and the wood should at once, be made over to him, unless required for the use of the department concerned, in which case the previous permission of the Inspector should be obtained.

12 Mulberry wood should not be supplied to the *paraos*, except on special occasions, such as journeys of *Deodhi Khas*, and Viceregal and other very large camps, and only then, if sufficient wood is not obtainable from other sources. When mulberry wood is supplied, the arrangements should be made through the Inspector of Mulberry Culture, who should receive as much previous notice, as is possible, and the wood should be transported under passes given by him. It should be accounted for to his satisfaction.

13 The rate of payment for mulberry wood, at *paraos*, is 2 Kharwars per rupee to be realised in cash, in the case of persons, not entitled to free fuel, in other cases, the Inspector can take a book credit in his accounts for the wood used.

14 Mulberry trees in cantonments, will be under the control of the General Officer Commanding, provided that the wood must be used only within cantonment limits.

15 No mulberry wood, if in possession of any State Department, (including the Public Works Department), can be shifted from one place to another place, without previous notice to the Inspector.

16 In urgent cases, (e g , a mulberry tree falling into a canal), trees may be cut, by order of the Sub-Divisional Officer of Public Works Department, without previous reference to the Inspector, who should, however, be informed immediately, through the Divisional Engineer

Any mulberry wood, so cut by the Department, from trees growing within Public Works Department boundaries, may be used for departmental purposes, if required, but only with the previous permission of the Inspector, which will not be withheld, without good reasons being given

17 All departments should be requested, to inform the Inspector, of any mulberry wood, now in their possession, and should be asked in future to refrain from acquiring such wood, and from moving it from place to place, without previous intimation to the Inspector, and his concurrence The Inspector is ordered to treat as contraband any wood dealt with otherwise than according to the above rules, the Inspector will detain it (any expenditure involved by such detention being borne by the Department concerned), and will communicate with the Head of the Department If he is unable to dispose of the case, in consultation with the Head of the Department concerned, he should report the matter to the Settlement Commissioner, for the orders of the higher authorities

18 The Inspector has authority to examine the Patwaris' records, for the purposes of his work

The following rules regulate the possession of cocoons, etc —

Rules regarding unauthorized possession of cocoons, etc , sanctioned by the Durbar and published in State Gazette, No 27, dated 14th October 1907

Whereas it is expedient to provide a law against the unauthorized sale or possession of silk cocoons and seed and the unauthorized possession or receiving of raw Kashmir silk, it is hereby enacted as follows —

- (1) This Regulation shall be called the Kashmir Silk Protection Regulation of 1903 (1906-07) and shall extend to the whole of the Jammu and Kashmir State
- (2) The words (1) "kirm kash," (2) silk seed, (3) silk cocoons and raw Kashmir silk shall have the meanings ordinarily attached to these terms in the Jammu and Kashmir State
- (3) Any "kirm kash" employed by the Sericulture Department, Kashmir, who disposes of by sale or otherwise in favour of any person, except the Director of Sericulture, Kashmir, or such persons as may be appointed by the said Director in this behalf, any silk cocoons reared by him and in his possession or any silk seed given to him for rearing by the said Director, or who wilfully neglects to deliver up the full quantity of silk cocoons reared by him, or to make over, if required to do so, any silk seed in his possession to the said Director of Sericulture or the persons appointed by him in his behalf shall, on conviction, be liable to imprisonment of either description for a term which may extend to three years or to fine or to both
- (4) Any person who, without any authority from the Director of Sericulture in this behalf, receives in any manner whatsoever, any silk cocoon or silk seed from any *Kirm Kash* or is found in possession of any silk cocoon or seed otherwise than under the authority of the Director of Sericulture or other person or persons duly authorized by him in this behalf, shall be dealt with as if he had dishonestly received stolen property knowing or having reason to believe the same to be such, and shall be liable to be prosecuted under section 311, Ranbir Dand Bidhi
- (5) Any person who receives or is found in possession of raw silk manufactured from cocoons reared under the authority of the

Kashmir Sericulture Department otherwise than with the permission or under the authority of the Director or other person duly authorized by him in this behalf shall, on conviction, be liable to imprisonment of either description for a term which may extend to 3 years or to fine or to both

- (6) Offences under this Regulation shall be triable by the ordinary Criminal Courts of the State in accordance with the Criminal Law and procedure of the State in force at the time

M. L. McNAMARA,

Director of Sericulture,
Kashmir State

APPENDIX VI.

The following reports deal with the industry in the Gangaw Sub-division of Pakokku, in Pymuna (Yamethin), in the Southern Shan States and in Toungoo

Note on the Silkworm breeding Industry in the Gangaw Sub-division, prepared by Mr. E. I. A. Hay, Assistant Conservator of Forests

1 The Taungthas and Shonshis, the latter a local race of Chins, allied to the Hakas who have emigrated to and permanently settled in the Upper Myittha valley are those who chiefly concern themselves in the cultivation of the silkworm though certain Yaw villagers are said to go in for it to a small extent

There seems to be no doubt that on the whole the Industry is not so widespread as it was. This state of things may be assigned to several causes, but chiefly to slackness though in at least one case the influence of an unusually orthodox pongyi has caused one village to give up the business (Thimbaya)

Some villages evidently take it up for a period and then drop it

2 The following list of villages is probably fairly exhaustive and, if made worth while the industry could very easily be widely spread in this valley

(Silkworm breeding is about to be introduced into the Haka-Chin Hills, the mulberry foodplant being introduced from Shonshi)

(a) *Villages producing silk*

Shonshi (Chin) 100--200 houses cultivate the insect during the rains, a few throughout the year

Hekchiba (Chin) some few houses throughout the year

Wetthet (Taungtha) a few houses cultivate it the whole year, sometimes many houses take it up

(b) *Villages formerly cultivating the insect, and probably spasmodically in the future*

Tanlungon (Taungtha)

Tawyaung (Taungtha)

Hingokkon (Taungtha)

Thanbaya (Taungtha)

(c) *Villages said to cultivate the insect*

Zahaw (Yaw)

Loubaw (Yaw)

Lonchon (Chin)

Kyaw (Yaw)

Mauklin (Yaw)

Zabya (Yaw)

Taungbyin (Yaw)

Magyikin (Yaw)

Shonshi is undoubtedly the most important village from the point of view of silk production, and to Shonshi come buyers

A rough estimate of the monthly output of silk by one silkworm breeding house would be 5 to 7 ticals, worth Rs 20 per viss

3 *The food-plant*—The food tree (*Burmese posa*) is a mulberry, almost certainly *Morus indica*, though I was unable to obtain any satisfactory description of the flower and most villagers seemed doubtful of there being one. Probably about one in ten trees only produce flowers. The fruit, like a small English mulberry, is at present on the trees (April 28th)

There are two varieties of the tree, which appear to differ only in the size of the leaf (Possibly they are two species, in which case the larger is probably *M. Lavigata*) The larger leaved variety is called in Burma *hmunma*, the smaller *hmunngale*. The tree seems to reach a maximum height of about 15'

Green leaves can be got all the year round as new leaves take the place of those picked for use

The mulberry is grown only in the villages, though it is also rarely found wild in the jungle. The leaves of both the wild and cultivated trees occasionally form an ingredient of curry. The fruits are sometimes eaten by children. The tree is propagated by cuttings in the rains. This tree forms the entire food of the worms

4 *The silk moth*.—There are two varieties of silkworms, the one producing white, the other yellow silk. Both are equally valuable. The larvæ of these two varieties are indistinguishable in the early stages of growth but later the larva of the former is said to be greenish and to bear lines on the body, and that of the latter to be yellowish and without lines. Both varieties of moth are identical

The duration of the various stages in the life-history are roughly as follows —

The egg stage (burmese *U*) about 8 days

The larval stage (bur *pogaung*) about 30 days.

The pupal stage (bur *po on*) about 15 days (a mean of very varying estimates)

The imagines (burmese *leikpya*) are thrown away as soon as egg laying is completed

During its whole life, the cultivation of the insect is carried on entirely indoors. The eggs are laid on a bit of cloth, and, on hatching, the tiny larvæ are transferred to a basket-work tray and mulberry leaves (sliced small, at first) introduced.

A cover of cloth is kept stretched over the tray. As soon as the cocoons are completely spun, they are put out in the sun to dry and are then placed in hot water

Death of the pupæ results, and the silk is easily wound off the cocoon. The dead pupæ are occasionally eaten. In order that the life-cycle may be continued, a stock (burmese *myo*) is kept and these pupæ are allowed to hatch out. Such cocoons, after emergence of the moth become useless and are thrown away, without the silk being removed.

The moths have completely lost the power of flight (pointing to long established domestication) and after copulation of the sexes, the females deposit their eggs on a piece of cloth provided for them. The moths are then thrown away.

The silkworm is never found wild and no explanation was advanced to account for its original appearance in this neighbourhood

The life-cycle continues throughout the year

5 *Diseases, etc*—The animal is subject to no disease, but the larvæ are kept covered over with a cloth, as a protection from the bites of ants and flies. The larvæ are also, to some extent, susceptible to the malignant influences of wizards and to the effluvium of frying fish

Silk in Yamethin

The Divisional Forest Officer, Pinyinmana, reports —

- (1) In this division sericulture is at present practised in the Yonbin and Minbvin Reserves at the following Villages —

	Household
Yonbin Reserve { Swedawmyaung	22
{ Chaungzu	2
{ Thavetchaung	1
Minbvin Reserve { Dalangyun	3
{ Sawwngyun	3

- (2) The silkworms are fed almost entirely on mulberry, but sometimes on "Mahlking" (*Morus Latigata*)
- (3) A rough estimate of the annual yield of silk per household is 8 viss and the price varies from Rs 15 to Rs 20 per viss, the silk weavers, however, do not trust entirely to sericulture for a living but engage also in cultivation
- (4) Every silk weaver in this division is an immigrant from the Magwe District. None of the local people go in for sericulture, but I think they would if they were encouraged
- (5) The only places where mulberry plantations are formed are on the flat sandy banks of the creeks, where generally one finds only 'Kang' grass, so they do not interfere in the slightest with silviculture. These flat sandy localities abound along every large creek in this division and I see no reason why they should not all be used for mulberry plantations. If villagers were allowed to form mulberry plantations along all these creeks and were generously treated as regards rent and taxation I should not be at all surprised if it resulted in a considerable expansion in sericulture in this division, especially in the Yonbin, Minbvin, and Palwe Reserves

Southern Shan States — The following is from A. E. Ross, Esq., Deputy Conservator of Forests —

I have the honor to inform you that as far as I have been able to discover sericulture is only practised to a very small extent in the Laklai Circle of Monghsit State and by seven Shan householders in two villages in the Laika State and by a few villagers of the Loi Ai and Loilong States living near the Paunglaung River, on the borders of Burma, where I am informed the breeders are chiefly Burmans or Yabems and treat the silk worms and cocoons in the same way as the Yabems of the Pinyinmana Sub-division, regarding which a Monograph was I believe printed some years ago. These Paunglaung villagers grow small mulberry trees called "Posabin" within easy reach of their villages yearly and collect the leaves daily for the silk worms which are bred in large trays containing cold cooked rice to which the plague of flies ('Polaungs,' 'Pyoks,' etc) have no access. It is on account of these flies, I am told, that the people are unable to breed silk worms on the mulberry saplings in their plantations in the Paunglaung. These villagers get their cocoons from Konhla a village in Pangmā State, where the mulberry tree grows well and where the specially bad flies found in the Paunglaung do not give trouble. Konhla is at least 2,000 feet higher than the Paunglaung villages

The first batch of eggs is hatched between February and March when the mulberry saplings come into full leaf. The silk produced is mainly yellow and of a shade like "tassar" and used to be sold in the bazaars at Rs 15 to 20 a viss and is mainly exported to weaving centres in the Yawngghwe Lake Valley and to Pindaya

2 In the Yawngghwe State silk weaving is an important industry and is carried on to fairly large extent, but practically all the silk used by the weavers is brought up from Burma and through Kengtung from the French

Laos country Sericulture is not practised in the Yawngkhwe Valley principally on the ground that the people are Buddhists and are opposed to taking life Mr. Browne Adviser to the Yawngkhwe Sawbwa, is of opinion, however, that the 'Inthas, who form a fairly large percentage of the population of the Yawngkhwe State and who eat beef and catch fish would probably take to sericulture if they could be shown that there was money in the undertaking and provided a species of silk worm could be bred on the Willow (probably *Salix tetrasperma*) growing in the swamps near the Lake villages, on land unsuitable for paddy cultivation Mr Browne is growing willows planted close together (6 to 9 inches apart) on such land for twigs for basket making, and would be glad to experiment with silk worms if he could be supplied with species which are most likely to be successfully bred on the Willow

3 Mr Browne informs me that outside the Yawngkhwe Lake area which is chiefly populated by Inthas, who are mostly cultivators and fishermen the people who would probably take up sericulture in the Yawngkhwe State are certain Chinamen and Karen Christians, and that the two persons most likely to take it up are U Set Cho, the leading Chinese merchant at Fort Stedman and Yawngkhwe and Maung Kazin, Deputy Inspector of Schools Both the above are said to have taken up land for agricultural purposes in the Yawngkhwe State and might be induced to take up sericulture, and grow mulberry trees in plantations

4 Having regard to the facts that the mulberry tree is not commonly found in the forests of this division, which are usually remote from villages, and is only found cultivated near villages here and there and that the people are generally bigoted Buddhists opposed to taking life, the Forest Department could do little to advance sericulture in the Southern Shan States As Mr Browne, Adviser to the Yawngkhwe Sawbwa has expressed a desire to experiment with silk worms likely to be successfully bred on the willow, I would suggest that the Imperial Silk Specialist may kindly be asked to send Mr Browne suitable seed, if available, direct At the lower elevations in the Yawngkhwe State away from the Lake area, I am of opinion that the mulberry could successfully be grown, and Mr Browne might be able to have experiments carried out under his supervision by the two men mentioned in my paragraph 3 above

5 The practice of sericulture is unknown in Kengtung State but much raw silk is produced in Siam and among the Laos to the East of the Mekong Most of the better quality silk sold in the Kengtung Bazaar is believed to come from China and from the Lao country

6 I regret that I have as yet received no report from the Assistant Superintendent, North Eastern, regarding the silk growing in Laika and Mongsit States as he has not yet had time to visit the villages where it may be carried on, but it is believed that the industry has almost died out Formerly the eggs were brought through Kengtung from China and possibly from the Lao country and grown on the Mulberry in small plantations near 3 or 4 of the villages in the Laklai Circle of Mongsit State, but the number of people engaged in it was small and none of them made it their sole occupation The silk used to be dyed sometimes with indigo and sometimes with saffron

7 If it is desired to encourage sericulture in the Southern Shan States I would suggest that the Superintendent and Political Officer may kindly be asked to assist The Forest Officer may not deal with the villager except through the Political Officer and Shan Chief and the forests where silk worms might be grown are for the most part not easily accessible and are usually some distance from villages

Laos Silk is produced in villages in the hills East and West of Yekong in the district the following extracts from a report by the Assistant Superintendent of the industry

1. *At the Little Tower Tip* This tract is situated about 20 miles north of the North End of Yekong a small station on the railway line

about midway between Rangoon and Mandalay. Its surface consists, for the greater part, of high hills with narrow, devious valleys between them. Every part is covered with forest of giant bamboos and tall evergreen trees. Pines, climbers, and herbaceous shrubs abound in the dense and tangled undergrowth. The virgin forest is still extensive, though generations of Karens have annually felled patches of it for rice cultivation. These clearings, known as *Yas*, are, in Leiktho, small in extent. Their average size is about 5 acres; frequently, however, they are only 2 acres, but sometimes extend to 8 or 10. Small sized *Yas* are, however, those that are the most commonly met with. These *Yas* are cut in rotation, with the period of rotation varying from 6 to 10 years, and, even though virgin forest be felled the clearings are abandoned after one year's cropping. Generally speaking in a locality, like Leiktho, which enjoys an abundance of rain in the year the rapidity of the growth of secondary forest speedily restores protection and fertility to areas that have been clear-felled for a season; so that, with practically little denudation of the soil, they are maintained in condition fit for crops by the long periods of rest they enjoy under cover of the new and fast growing forest.

When, at the commencement of the rains, the *Yas* are cleared and sown with rice a few mulberry cuttings, too, are put down. The cuttings strike root and the resultant plants are left to themselves until the beginning of October, when sericulture on the *Yas* is taken in hand. Silkworm eggs (seed) are then purchased from those who might have them to spare among the Karens, or from traders who hawk them about in the season. No system seems to be followed beyond feeding the worms once they hatch out. Almost every family raises at least a viss or two of silk in the year, and, from one to six broods are grown in the season, October to May. This is the best season in Leiktho, the rains are said to be damp and unhealthy and the brief hot weather, likewise, injurious. When the *Yas* are abandoned at the end of the rice season, the mulberry bushes, too, are abandoned, but, fresh cuttings, taken from them, are set out on the *Yas* of the ensuing season. The mulberry grown is the common white var variety *Morus alba*, var *indica*, Linn and the silkworm itself is a greyish white creature which is probably a species of *Bombyx*. With a view to establish the identity of the species, I brought away several cocoons from Leiktho which have been made over to the Assistant Entomologist. Mr. Shroff is also engaged in rearing a very large brood of young caterpillars that hatched out from eggs brought in by me from the Ayodanng village (Yabem Tract). There seem to be two varieties of the worm, distinguished by white and yellow cocoons. The Leiktho cocoons are small and ill-shaped, doubtless, due to the under-feeding of the worms and the general absence of care in their breeding. The cocoons, with the chrysalises inside them, are thrown into pots of water and boiled. Whilst boiling, the silk is unravelled and spun on to a wire spindle by means of an iron-handled bamboo wheel. From this, when dry, the silk is reeled on to cross-beamed bamboo spindles. The silk produced is seldom sold, but is locally used chiefly for the weaving of the bright coloured strips that form the centres of the longyis or tamams of the women. These strips are about $1\frac{3}{4}$ yards in length and from 18 to 20 inches wide each. Besides this, the silk is made up into bags, belts, coats and trousers. The coat-and-trouser silk is usually white, but that for the other garments and articles is variously coloured.

At the time of my visit (last week of April) silkworms were being raised for seed only in one house in the Kmainglon village. The only tray I saw there was a common sagaw (sieve) made of bamboo. It was about $2\frac{1}{2}$ feet in diameter with a 2 inch high border running around it. The worms in it were said to have been 20 days old at the time I saw them. They were then about one inch in length and otherwise puny for their age. There were thousands of them in the tray in which they were huddled together many layers thick. They were fed only twice a day, though the flourishing mulberry bushes in the garden were capable of furnishing crops of leaves sufficient to feed them at least four times daily. The cloth with which the tray was covered was one of the filthiest I had seen, it was intended to keep off the

myriads of flies that buzzed around the wretched worms! If this culture be taken as typical of the treatment which is generally accorded to silkworms in the township, it is no wonder that the cocoons are small and the silk itself somewhat poor and flimsy. But such as it is, I was told that the worms mature for silk in a moth from hatching out and that the silk itself, in the raw state, is worth from Rs 12 to Rs 15 per viss.

2 *The Yabern Tract*—This tract lies to the west of Yedashe, about 30 miles beyond the railway line. It is a dreary country of moist, malarious, ever-green forest mingled with tall teak trees and large bamboos. It is much cut up by narrow streams that wind in and out at the foot of the hills. The road I took crossed the Lonyanchaung at least about a dozen times in a distance of only 8 miles. The mulberry, which is of the same species as that which is grown in Leiktho, is raised in little patches, of a few square feet each, on the silt of the river bank (Swa River) above flood-level. At the commencement of the rains cuttings from 6 to 12 inches, or thereabouts, in length are made from branches which are as thick as a lead pencil. These cuttings are set out in the silt at a slant of about 30 degrees with the horizontal. The cuttings are 2 to 3 feet apart. No attention is said to be given to the plants which readily shoot up in the moist earth. The plantations furnish leaf for feeding almost at once and last from 2 to 3 or 4 years, after which, they are abandoned for fresh ones. The arts of coppicing, pollarding, and pruning are unknown. Seed is purchased at the commencement of the season (first week of June) from traders, usually from Letpwegyi or Letpwegale, on the Myohla side, who hawk them about the villages of the Southern Swa Tract (Yabern Tract). Almost every village in this tract engages in the production of silk, and nearly every villager understands the raising of the mulberry and the rearing of the silkworm. Seed is purchased at the rate of 10 discs per rupee. A disc of seed is said to be the product of 17 fecundated female moths, which, on separation from the males, are placed, for a night, on soft paper within 3-inch-wide circlets of palmyra leaf-blades. The minute eggs are yellow in colour and are closely packed on the surface of the paper. The eggs turn dark grey before hatching out. The worms emerge in 8 or 10 days after the eggs have been laid. They are then little brownish creatures that swarm in the trays in which they are placed. The breeding trays in the Ayodaung village are 3 feet in diameter, neatly made, with a 3-inch-high rim running around them. They are circular in shape, like common sagaws, and are made of closely-woven bamboo slips. A rupee's worth of eggs is said to be sufficient to stock five or these trays which, if properly tended, are said to yield not less than half a viss of silk, worth from Rs 9 to Rs 10. When the worms hatch out, they are fed, for the first 5 days, upon the softest and youngest mulberry leaves. At the end of this period, they moult for the first time, after which they are fed upon mature leaves. The worms are said to moult five times in the 21 days of their larval stage. They increase in size with every moult and are fed from 4 to 5 times daily. The trays are cleaned out during the moults, when no food is either given or taken, no feeding, too, is done at night. The cocoons are spun on the 22nd day, and the moths emerge on the 8th, 9th or 10th day from spinning them. When the worms turn yellow after the last moult and show symptoms of restlessness, they are transferred from the breeding to the spinning trays. These trays are about 6 feet in diameter, with open-work bottoms to admit the air. Inside them, and coiled edgeways over the inner surfaces, are placed very long open-work ribbons of bamboo, and it is between the helix-like coils of these ribbons that the worms are placed to spin. The cocoons are said to be spun in a night. The moths, which are white, are not very active, the males are smaller than the females and seek the latter directly they emerge. The couples are mated only for a day, when, the males being thrown away, the females are placed within the circlets of leaf to lay. The eggs, too, are said to be laid in a night after which the moths are thrown away. Swa silk, then, is produced in from 40 to 41 days from the date of the laying of the egg—

In the egg	8 to 10 days
In the larval stage	21 days
In the cocoon	8 to 10 days

During the breeding of the worms, the Yabeins give them every attention. They feed them from four to five times a day, the breeding-trays are large and airy, there is no crowding, and the trays are protected from dust and insects by being carefully covered over with cloth. The cloth is still far from clean, but it is an improvement upon the rag of the Karen. Moreover, though, like the Karen, the Yabein, too, has no special building to breed the worms in, the trays are suspended by string from the roof, or are placed upon bamboo racks that hang down from the rafters of the dwelling house. Ants are prevented from crawling down into the trays by the points of suspension of the racks being smeared over with crude earth-oil or other oily substance. No silkworm diseases are known in the tract. The separation of the silk from the cocoon is done on the Po-danyin, a rude hollowed-cut wooden wheel with a long handle attached to one side of it. To this wheel the silk is reeled from the cocoons which, as in Leiktho, are steeped in pots of boiling water. It is then reeled again on to the Po-yahat, which is a curious spindle consisting of 8 spokes and 4 bairs. Swa silk is said to be better than any other, excepting only Pong-loung silk. The cocoons, which are both white and yellow, are about an-inch-and-a-half long, they are evenly formed, oval in shape, and are full of silk of much softness and strength. Swa silk always sells at from Rs 2 to Rs 5 per viss more than any other silk in the district. Of late, the Yabeins have, I hear, taken to Ya-cutting on a large scale, to the neglect of the silk industry, to a great extent. In Ayodaung, for instance, only 5 out of the 19 families and, in the neighbouring village of Thagyibauk, only 4 out of the 12, engage in the raising of silk at present. This circumstance is regrettable.

3 *Karenchaung and Nagyat*—The mulberry is grown in both these villages, in the former as a hedge-plant, in the latter as silkworm fodder. In both places the plant flourishes as it seldom does elsewhere in the low-country, in both silk, too, it is said, used to be raised on a large scale in former times. The cause, or causes, of the decadence of the industry is unknown to the natives there. In the Nagyat village I saw at least one good plantation of mulberry trees, from ten to fifteen feet in height, which, though much neglected, are still well preserved. Enquiry here revealed the fact that, until Cholera decimated the population a few years ago, silk was one of its chief industries. At present, there are only three families who engage in it to any extent, though the profits are said to be remarkably good. In Nagyat, silk is raised throughout the rainy and cold weathers. The mulberry and silk are the same as those that are raised in Leiktho and the Swa tract. The silk produced is said to fetch Rs 14 to Rs 16 per viss, as raw silk, but when woven, fetches a better price. It is usually woven into women's longyis. These tameins, as they are called, are each $3\frac{1}{2}$ cubits long and 20 inches wide. It is said that as many as 9 such tameins can be woven from a single viss of silk. The tameins sell at from Rs 3 to Rs 5 each, so that, the produce of a single viss of silk sells at from Rs 27 to Rs 45.

* * * * *

Suggestions for Improvement and Extension

1 *In the Leiktho Township*—The Leiktho Karens, large numbers of whom I addressed through their elders and headmen as well as through Fathers Conti and Pacati (Roman Catholic Priests of the Italian Mission to the Karens), expressed much willingness to engage in the production of silk on a large and systematic scale, provided the Government undertook to help them in the industry. The question as to whether, in their backward condition, the Karens would take to Sericulture in preference to Ya-cutting, is one which time alone can answer. To endeavour to make a whole tribe to unlearn practices which to it are like instincts, will necessarily be fraught with very great difficulty. The task of improvement would appear, at the start, to be beset with obstacles peculiar to the Karen. The prodigality of Nature in the region he inhabits—the ease with which, with little labour and less care, crops can be raised to meet his requirements—has made of the Karen a lazy

man When he has cleared a patch of forest and sown it with grain-crops, he seems to feel that he has fulfilled his every expectation and whole duty in life! His love of ease, indolence, ignorance, and natural distrust of things, however good, that are new, but, above all, his happy contentment of mind, will be extremely hard to wean him from But he is naturally intelligent, quick of imitation, and has shown himself able to discern and appreciate things that are likely to prove to his benefit For instance, when the coffee industry on the Leiktho hills, which was started by the Priests some years ago, began to flourish and yield good returns, the Karens readily took to it and opened out several plantations of their own which thrived exceedingly until destroyed by the Blight

* * * * *

As regards silk, I desire to point out that the advantages of Leiktho for the extension of the industry appear to me to be the following —

- (1) The knowledge, though indifferent, which the Karen already possesses in the raising of the mulberry and of the silkworm
- (2) The presence of extensive areas of suitable land for the establishment of permanent mulberry plantations
- (3) The complete naturalization of the *Morus indica* in Leiktho
- (4) The climate of the locality which is favourable for Sericulture

In the presence of these facts, I would recommend —

- (1) The establishment of carefully-laid-out plantations of mulberry in at least six of the more important silk-growing villages These plantations should be permanent estates, to be conserved and managed, like Communal Forests, for the common benefit of each village-community They should aim at the production of the largest trees that would be capable of yielding regular crops of leaf to meet every important requirement of sericulture The areas of these plantations will, of course, depend upon the total average number of individuals who would be found in each village or group of villages prepared to undertake systematic sericulture, subject to the control of expert supervision
- (2) The establishment, in suitable localities, *e g*, Shwenangyi, of model silk farms or dépôts for the production and distribution of good, healthy seed, the demonstration of improved methods of breeding, and of reeling, spinning, and the other processes involved in the production of raw silk of good quality The dépôts should also, as far as possible, experiment with new varieties of silkworm, and small areas near them set apart for the experimental cultivation of other varieties of the mulberry, because, of all the facts connected with the industry, we are at present least certain as to whether the worm and plant now raised in Leiktho are, economically, those that are the most suited to the locality
- (3) The necessity for the services of a trained Forester and of an expert Sericulturist are, of course, indicated in the suggestions I have made above, for, I am inclined to the belief that, without some assurance that so important a matter had been consigned to the immediate control of competent persons, it would be futile to attempt its serious undertaking
- (4) It is also imperative that a suitable market be secured for the product directly it is available, otherwise, its economic production is likely to suffer, particularly in its continuity

2 In the Yabein Tract—Though he produces one of the finest of Burmese silks, the Yabein, in his methods, leaves much to be desired He is,

after all, only a little better than the Karen, his silk is still coarse and wanting in gloss, the breeding-trays are still housed in the dwelling-hut, the machinery used is of the rudest description, there are no permanent mulberry plantations, so that, leaf-production is still a precarious matter. In these circumstances, I would recommend —

- (1) The placing of the Swa silk-tract, too, under expert surveillance
- (2) The encouragement of the production of silk and the discouragement of Ya-cutting in the tract
- (3) The opening out of the permanent mulberry plantations and their conservation and management, as suggested for Shwenangyi

The work of the experts in the Swa tract would take the shape of over-seeing and advice rather than of direct help in the industry, sympathetic aid and guidance, it is, that appear to be indicated in the Yabein tract, therefore, I find insufficient reason as to why the two experts recommended for Shwenangyi should not also suffice for the Yabein tract

3 *In the Low Country* — Though the natural facilities for the expansion of Sericulture in parts of the low country seem to be good the possibility for its immediate extension appear to be both poor and remote. As has been already stated, the mulberry flourishes at Karenchaung and Nagyat. Both these villages are situated on the left bank of the Sittang river. They have mixed populations of Burmese, Karens, and Shans. In both Nagyat and Swa it is the Burmese that raise silk, though the chief objection raised by them elsewhere in the low country is said to arise from religious scruples against the taking of life by the Buddhist. This refers to the boiling of the cocoons for the reeling of the silk, whilst the chrysalides are still enclosed in them. As the objection is based on religious belief and as there seems to be no method now known by which the silk could be reeled without destroying the chrysalides the prospect of the expansion of sericulture in the low country is, as I have said, very problematical.”

APPENDIX VIII.

CLIMATE TABLES

In the following pages figures are given which represent the climate for each month for a number of localities arranged in the order of natural divisions as listed in Appendix VII. After the District, the elevation in feet is given. The first line represents mean maximum temperature for each month from January to December, the second represents mean minimum, the third represents mean humidity at 8 A.M. and the fourth wet bulb for the mean of the day. The figures are copied from Memoirs of the Indian Meteorological Department No. XXII, Part III (1911) or obtained from Dr. G. T. Walker, Director General of Observatories, and have been added to and brought up to date by Dr. Simpson. Figures in italics indicate unsuitable conditions.

In some cases a fourth line is added which is the wet bulb mean. Dr. Walker, suggested that instead of using the factor maximum humidity as an index of suitability ($85 > 85$ being near the limit at which worms will grow) the wet-bulb figure alone should be used.

Examining districts in which we know the behaviour of silk worms, whenever the wet-bulb 8 A.M. mean is here over 75° , the conditions are unsuitable on account of excessive humidity and temperature.

There are three conditions in which sericulture is impossible—

- (1) Mean maximum for the month 100° F. or over,
- (2) Mean minimum 50° F. or under and
- (3) Mean wet-bulb 75° F. or over

Whether a mean humidity under 50 per cent without the temperature being over 100° is also a limiting condition is not clear, but it probably is.

It is a distinctly limiting factor that in wet areas trays must be used and the cost of these will knock out silk unless at least two broods are got, preferably more. This does not apply to dry areas in which a brood can be got without trays and so one brood alone pays.

This must be kept clearly in mind in all districts, where say the rains are cool and allow of sericulture. If this period will not allow of several broods it is probably of little use.

So too rain on leaf is a bad factor and continued feeding of wet leaf will lead to disaster.

For very many districts, nothing but a definite experiment will tell and it will be well to systematically test all areas. Do it by—

- (1) selecting best time,
- (2) „ place with population,
- (3) planting mulberry,
- (4) erecting small house or renting one,
- (5) putting a fieldman there to rear, employing a family on wages for it,
- (6) getting broods of the proper race and either selling them or having them reeled elsewhere,
- (7) discussing results with local officers and finding out weak spots

APPENDIX X.

OCCUPATION FIGURES.

The tables below enumerate the number of persons recorded in the Census of 1911 as engaged in Raising Small Animals, Silk Spinners and Weavers. The first table is a summary of the provinces to which are added two columns, the second and fourth, into which are put figures estimated as actuals the letter T prefixed in column two means they are Tasar rearers. In column one in summary table, the figures are often misleading. Mysore records 508 rearers when there are probably 70,000 actually, who were classed as agriculturists and in such cases the figures in column one are omitted in the Total Column.

The second and fourth are added as estimates of the real numbers engaged

PROVINCE	SUMMARY

APPENDIX XI.

SUMMARY OF EXPERIMENTS.

ASSAM, MANIPUR

*Note on Silk Industry, by Colonel Shakespear, Political Agent,
1st August 1916*

Silkworms were formerly grown in six villages, in each of which there were three or more Panjis, each of whom had to give annually 1st quality—"Muga"—16 tolas, 2nd quality—"Langyar"—20 tolas, 3rd quality—"Pangang"—40 tolas—(chassam)

In return they were exempted from *begar* for the three months when the worms lived and no other village might do silk. They reared univoltine races. The family that grew silk wove the thread also. The industry is now dying out and the imported silk is being used.

It is asserted that Manipuris were carried off into Burma and started the industry there. (See "Silk in Burma" by J. P. Hardiman.)

The Manipur Silk Company, was started by Anderson Wright & Co., but it failed owing to the following causes —

- (1) Experiments had not been made yet. The climate is very variable (and the mulberry would not grow well in water logged soil in wet weather)
- (2) Only one caste will do it, *i.e.*, Lois, the others who did it were people in debt or hard up
- (3) Initial cost is heavy. Each rearer had to have much help, a house, cattle, etc
- (4) Risks of disease, etc

The industry was handed over to Manipur Government in 1912

Note on its results by Mr. Blachie

29/3-77 oz Italian-Japanese gave 10 maunds, 32 seers green

20/4-60 oz Italian-Japanese gave 4 maunds

27/4-40 oz Nistari gave 3 maunds

24/5-40 oz Nistari gave 10 maunds to date

(2 oz gave 1 maund, 16 seers)

These results are not at all promising

ASSAM, KHASI HILLS

From the Annual Reports of the Agricultural Department

The Director of Land Records and Agriculture was sent to Kashmir in 1903. In 1904 an experiment was made with two ounces of European seed in Shillong and 2 in Kohima. The outturn is not known but the green cocoons were valued at Rs 80 per maund. The experiment was repeated at Shillong in 1905. Several Khasis took seed. The total yield of green cocoons at the farm amounted to 1 maund 14 seers, the Khasis obtained an outturn of 26 seers. In 1906 the leaf suffered from frost and 27 seers of cocoons were produced. An attempt was made to get Khasis to grow mulberry. (An account of the progress to date and of the chances of sericulture in Assam will be found in *Agricultural Journal, India, II, Part 1, January 1907*). In 1907 local as well as imported seed was used. Ten and a half seers of cocoons were produced. No Khasis would do sericulture. In 1908 Khasis again took an interest in the subject of silkworm rearing. Thirty-two seers of cocoons were got from $\frac{3}{4}$ ounce of seed. In 1909, $\frac{1}{2}$ ounce of seed gave 21 seers and 2 chittacks of cocoons. In 1910, $1\frac{3}{4}$ ounces of seed gave 1 maund and 18 seers of

cocoons In 1911, $\frac{1}{4}$ (? $2\frac{1}{4}$) ounces of Italian seed gave 2 maunds, 11 seers and 12 chittacks of green cocoons and $1\frac{1}{4}$ ounces of Var seed gave 1 maund, 37 seers and 10 chittacks of green cocoons In 1912 the Sericultural operations were transferred to the rearing house of the Roman Catholic Mission, Shillong An outturn of 3 maunds and 3 seers of green cocoons was obtained from $2\frac{3}{4}$ ounces of seed In 1913 the rearing was commenced with six ounces of Var seed but all failed In 1914 four ounces of seed was used, the outturn has not been stated In 1915 four ounces of eggs were reared and they produced $3\frac{1}{2}$ maunds of green cocoons

The outturn per oz is usually not given Good cocoons can be got if—

- (1) hatching is regulated,
- (2) there is leaf,
- (3) rats are kept down

SHILLONG

The Khasi Hill experiments have gone on for 10 years and show that good quality of cocoons can be grown, that locally produced seed is free of disease and that, with present results, the Khasis will not touch it

The site is an absolutely unsuitable one in my opinion, the rearing house is not a good one, the leaf is poor, and the whole course of the experiments has been bad What could be done with a proper plantation, proper seed and incubation, two or three broods a year and good rearing has yet to be seen Above all, one wants to try industrial rearing without nets and trays

The experiments show again the futility of isolated experiments done without real expert advice

In 1834 or 1835 Mr Scott introduced reelers, reels and plants of the *Morus alba* from Rungpoie to Darrang and started a filature The experiments failed for want of European supervision and on account of the death of Mr Scott (*Geoghegan*)

HILL TIPPERAH

From A Choudhury, Esq, Officer-in-charge, Agriculture Department, Agartala

Dated the 29th July 1916

The experiments in growing mulberry and rearing cocoons were fairly successful in the Kasipur Farm and the silk produced was fairly good and obtained good price in the market But the business could not be run on commercial basis and the local people could not be induced to take to the industry and expert opinion obtained indicated that silk might thrive only as a minor cottage industry The expenditure grew disproportionate to the success achieved and the experiments were accordingly given up Mulberry is still growing on the Farm-lands But no use is being made of the crops

NEPAL

From Lieutenant-Colonel S F Bayley, Resident in Nepal, Nepal

Dated the 2nd August 1916

His Excellency the Prime Minister of Nepal, has, while thanking the Government of India for their offer of help and advice replied that there is no intention at present of starting any silk industry in Nepal, nor has he any information available which could usefully be conveyed to Mr H Maxwell Lefroy An attempt at introducing sericulture was started some years ago at Buginj near Raxaul but as it failed to show or give hope of good results it was soon abandoned and no details are now on record concerning it

J22
Bihar and Orissa

In 1877 agricultural experiments have been carried out from 1877 to 1878 at Government expense under the supervision of the Executive Engineer of the Bihar and Orissa. The amount spent and the outturn was as follows —

6 seers 15 chittacks	}	Value Rs 318-11 6
20 " 14 "		
1 seer 0 chittack		

*Silk
Chassam
Cocoons*

The number of trees planted was 16,016

LIOTARD

In 1867 mulberry worms were grown at Biheea in Shahabad. Mulberry grew well. Bengal multivoltine species were grown but failed because (1) difficulty of getting good seed and (2) mortality in the worms

GEOGHEGAN

UNITED PROVINCES

Dr Bonavia in Oudh 1861-63

He distributed China mulberry cuttings in Oudh freely and plants grew well. Silk produced in 1862 was equal to the best China silk.

In Fyzabad an experiment with Kashmir silkworms was made, but the worms deteriorated in the succeeding generations (Probably from disease). In Sitapur, the China Nistari worm, Deshi Bengal Chotopolo worm, freshly imported Kashmir worm, were tried. High hopes of success were raised but the experiments died "after the personal example of its zealous promoters was removed from their eyes."

Dr Bonavia concluded that the Kashmir silkworm could produce good silk in Lucknow.

"The Oudh experiments were a failure, partly because they were not conducted continuously on one centrally directed plan, and partly "because of the disease then not being understood"

(Monograph on Silk Fabrics in North-Western Provinces and Oudh)

The Kashmir worm must have been that indigenous to Kashmir and not the present imported variety.

DEHRA DUN

In 1871 Captain Murray started with multivoltine and univoltine species in Dehra Dun. He planted mulberry trees, but afterwards he relinquished the business. In 1872 Mr H. G. Ross, Superintendent of the Dun took it over. In 1875 he got four seers of silk to the maund of his cocoons. The silk was white. In 1877 he started again and the silk was good. In 1878 the operations were still more successful. He reared Kashmir, Japan and acclimatised Japan seeds, and 44 lbs of silk was reeled off. In 1879 there was failure, which is due to eggs hatching prematurely. In 1880 Mr Lepper of Lister & Co came and started operations and the estimated outturn was about 30 maunds of cocoons. In 1881 a grant of land 3,472 acres in extent was assigned to Messrs Lister & Co at Majri in the Eastern Dun. The net result of the operations was a produce of 12 maunds, 24 seers raised by villagers and 8 maunds and 13 chittacks, by Messrs Lister & Co. In 1882 more trees were planted and the price paid for green cocoons was reduced from Rs 40 a maund to Rs 20 a maund. In 1884, 15½ ounces of seed gave 13 maunds and 18 seers of cocoons. *They now took to rearing in large houses.* Twenty-seven houses were built each 100 feet x 20 to 24 feet. From 1884 to 1890, six to seven lakhs were spent extravagantly. Filatures were erected. The sum of Rs 36,000 was spent in one year. At length in 1896, Mr Pink

resumed charge and started to get tenants to rear silk worms. In 1899, 80 tenants were rearing worms. The position was more hopeful now than before. Two and four maunds of raw silk and 5 maunds of chassam were sold. In 1902 the scheme was wound up and the land was resumed by Government. The land is now being worked as a zemindari.

In February 1916 I saw Mr MacMullen, employed on the Lister Giant 1888-89. Good results were obtained one year when they had fresh French and Smyrna seed. They took seed from their moths and sent it to Mussoorie. Next year all failed from pebrine.

Ultimate failure was due to—

- (1) Ignorance
- (2) Insufficient leaf
- (3) Leaf huddling late and rearing going on to the end of April
- (4) No nets or cleaning
- (5) 12 oz seed in one house 100 feet \times 20 feet, where only 4 oz should have been done
- (6) Want of labour. They had had villages but when they started these big houses, they hired labour, paharis from Mussoorie.

He thinks the silk practically stopped in 1890. Cost of staff, etc., in one year was Rs 36 000. There were 1 000 acres in trees planted in tall grass which was cut down every year and left there. There were constant fires in this grass.

KALAKANKAR

Raja Rampal Singh grew silk at Kalakankar. He reared *Deshi* Bengal-Chotapolo, Nistari and Eri. No results are given. Apparently they were going on in 1899 too. Pandit Darshan Lal Dube reports that the operations gave a profit of 12 per cent and ceased on the death of Rajah Rampal Singh.

Extract from the Partabgarh District Gazetteer —

The manufacture of silk in this district is of considerable interest. It was initiated in 1896 by Raja Rampal Singh, who in that year started a factory at Kalakankar, while a second was subsequently opened at Dharupur. A full account of the experiment up to 1899 may be found in the "Monograph on Silk Fabrics." Both the (Bengal, *Bombyx fortunatus*) and the Madras (*Bombyx ciosis*) silk worms were imported, and also the eri (*Attacus ricini*) worms from Assam, and no further innovations have been made in this direction. The first two varieties are fed on the leaves of the mulberry, and the last on the castor-oil plant. From these two classes two different kinds of silk are manufactured. The eri silk, though of great strength and durability, does not command a ready sale in these provinces, and further the local weavers are incapable of turning material equal to that of Assam. Consequently the manufacture is only conducted on a very small scale. The outturn of mulberry silk, on the other hand, has considerably increased, and the reeled silk finds a ready sale at Benares, fetching from Rs 12-8 to Rs 15-8 per seer, which yields an average profit of Rs 3 per seer. Most of the silk is sold in this form, but a certain amount of silk fabric is made on the estate. The workmen have been efficiently trained, and the industry also affords a means of subsistence to many boys and old women who are employed in spinning the silk from the eri cocoons and the waste mulberry silk. In order to increase the outturn, the Raja has laid down several plantations of mulberry trees. Two varieties are cultivated. *Morus niara*, the mulberry of these provinces, which grows into a tree of considerable size, and is planted in rows with a distance of some 30 feet from centre to centre, thus permitting the intervening land to be cultivated, and the *Morus alba*, a small shrub from Bengal, which requires constant attention and will only grow on good soil. The Raja allows tenants

to hold the land for the cultivation rent-free, paying for the leaves of the mulberry and permitting the tenant to retain for himself any other crops that may be raised, but the system has not as yet acquired popularity. There are now rearing-stations for silkworms at Jajupur near Kalakankar, Rampur, Dharupur and a neighbouring village, Purahasi.

PUNJAB

Umballa, 1836 —In 1836 mulberry trees were planted which thrived well. Worms reared were healthy. When Dr Gordon left the place no one took any interest.

Ludhiana, 1836 —In 1836 Sir Claude Wade started experiments but he was transferred from Ludhiana and no one started after him.

Mandi, 1848-49 —In 1848-49 silkworms were introduced in this State and they thrived perfectly.

Hoshiarpur, 1852 —Colonel Abbott commenced operations in 1852. He got a seer and a quarter of seed and the outturn was 56 seers of cocoons. The undertaking was given up on account of Colonel Abbott's departure for England.

Soojanpur, Pathankot, 1855-58 —There was a colony of Musalman rearers.

Gurdaspur, 1854 —Jaffer Ali commenced in 1854 and continued to 1864 at least.

Rawalpindi, 1858 —Experiments were made in a village Sauidpoor. Five or six seers of raw silk was obtained every year for several years.

Lahore, 1853-56 —Large experiments have been made in Lahore, first with Bengal multivoltine, then Kashmir worms. They all failed owing to bad feeding and dry heat. Eight hundred lbs of cocoons gave 80 lbs raw silk.

Amritsar, 1859-60 —Acclimatised, Kashmir, Bokhara seeds were reared, and they got mixed. The results are not given. The experiment was continued from 1861 to 1864. There was a total failure one year. In 1864 there were 8 to 10 maunds of cocoons.

Peshawar, 1863-64 —A silk experiment was made at Peshawar in 1863-64. 185 tolas of eggs were distributed at three places. Twelve seers of seed cocoons were set apart and yielded 115 tolas of eggs. The total quantity of raw silk was 25 lbs and refuse, etc., 60 lbs. A big scheme was put up with the intention of using 635 tolas of seed. The Company was formed and it paid 42 per cent to the shareholders. The Manager went home and all ceased.

Googaria (Montgomery), 1863 —A trial was made in Googaria in 1863. Five tolas of eggs were used. They yielded 9,709 cocoons weighing 1,524 tolas. The cocoons were very good.

Shahpoor, 1864 —An experiment was made at Shahpoor in 1864. 17 tolas of eggs were used which gave 78 lbs dried cocoons and 10 lbs seed cocoons, or say 400 lbs green cocoons. 16 lbs reeled silk sold for Rs 117-0-0.

In all these experiments there are these points —

- (1) Inexperienced officers (European) did them. They learnt a little and were transferred.
- (2) Eggs were from varied sources and were often mixed.
- (3) Hatching was long continued.
- (4) Methods of rearing were very odd.

But good cocoons were produced. (Geoghegan)

A very detailed account of the experiments made in Gurdaspur, Kangra and neighbouring districts between 1865 and 1882 will be found in Liotard—

Silk in India The conclusion will be found in Hailey's Monograph of the Silk Industry in the Punjab, (1899)

In 1865, Mr Montgomery reared silkworms in Kangra and planted Chinese and Philippine mulberry as the local variety did not suit the worms. He eventually got cocoons valued in London at Rs 300 a maund of dried cocoons. In 1872 Mr Halsey commenced in Amritsar and from 24 oz seed obtained 79 lbs cocoons per ounce. In Gurdaspur, the already existing rearings increased from five to fifty and Jaffer Ali was increasing his operations. Mr Halsey also started in Guddaspur the Punjab Government sanctioned a grant of Rs 1,000 for prizes to be given at an exhibition, which took place first in 1876. (These were not only shows but sales, the cocoons being then sold. Nearly the whole output probably was sold then.) Full details of subsequent progress will be found in Liotard. In 1877 a show was also held at Nupur in Kangra, a great deal of China mulberry was planted out in both districts and there was an extension of sericulture.

In 1879, Mr Halsey died and Mr Keighly of Messrs Lister & Co. tried to take over the former's interests. In 1880 exhibitions were held in Kangra and in Guddaspur, a sum of Rs 1,250 was spent in Kangra and Rs 960 in Gurdaspur on prizes, etc.

In 1881, a joint show was held and Gurdaspur exhibited 309 maunds 15 seers cocoons from 98 seers seed, Kangra 37 maunds 27 seers from 9 seers 8 chittacks. The former is at 8 lbs dry cocoons per oz the latter 10 lbs. These figures are less than those obtained at present.

In 1882, Gurdaspur showed 230 maunds, Kangra 40, Amritsar 6, Sialkot and Hoshiarpur less than 1 each. Disease had appeared seriously and was affecting the worms. Pebrine had not then been recognised in India and the issue of disease-free seed had not begun.

In 1883, Captain Bartlett, who had a filature in Kangra, died and the immediate market for cocoons came to an end. The disease continued, the number of exhibitors to the exhibitions diminished and in 1890, the exhibitions ceased. Messrs Lister & Co. had leased the trees from the district authorities and had done a great deal to induce cultivators to take up the industry, but finding the cocoon supply lessening, and that disease was spreading from the villagers' worms to those hatched from imported seed, they made the fatal mistake. They built large rearing houses at Gurdaspur, Gulpur and Sujampur in order to rear the worms properly. In 1892, Messrs Lister & Co. closed their rearing houses and concentrated entirely on their effort at Dehra Dun. The Kangra industry gradually died out, and in 1898-99, the rearing was almost at an end in Gurdaspur.

These experiments led eventually to the condition of the industry as it now is and the chief organiser is Khan Bahadur Ghulam Sadiq of Amritsar. This is dealt with under the Punjab in Chapter V of Volume I.

Reading the accounts of the Punjab and Kangra industry one can realise what can be done by personal influence and organised effort directed to the people themselves, and had it been that the question of pebrine was understood, the industry in these districts might have grown to very large proportions. The essentials of success clearly are a market for cocoons, an organisation to distribute seed and encourage tree planting, and public recognition and encouragement of the industry in the form of the exhibition and the prizes.

A SHORT NOTE ON THE SERICULTURAL OPERATIONS IN PATIALA STATE

It would perhaps be interesting to give a short account of attempts at rearing silk cocoons in the State prior to the creation of a regular Sericulture Department.

There are no definite records to show the results of experiments made from time to time but from the information available it might be stated that before the year 1912 the State had been approached by General Booth Tucker of the Salvation Army regarding the leasing out of mulberry trees in the State, particularly in Pail Tahsil, to the Salvation Army for their Sericulture propaganda. A lease was subsequently granted by the State to the Salvation Army for a period of two years. At the expiry of this period the State decided to start a Sericulture Department of their own and experiments were made by the Forest Officers of the State on a small scale by rearing some silkworms (*Bombyx Mori*). Attempt was also made to produce silkworm seed locally but as was inevitable this attempt proved a failure.

His Highness the Maharaja Sahib Bahadur, most keen and interested as he is in the development of the resources of his State and to encourage profitable industries, took up in right earnest at this stage the question of starting Sericulture in his State and decided to send to Europe a suitable person with some practical knowledge to receive proper training in various branches of this industry, with a view to start and organise a proper Sericulture Department on his return. L. Wazir Chand, who had received practical training in Jammu Sericulture Department of the Kashmir State and had done some experimental work in the Alwar State also was selected for the purpose and deputed for a course of two years' study in France. He returned to the State in January 1914 and was appointed the Director of Sericulture Department and with his appointment started the proper organization of a regular Sericulture Department.

In the beginning of 1914 Sadar Wazir Chand made an experiment with one ounce of eggs which he had brought out with him from France, reared these at his residential quarters and obtained 16 seers of cocoons.

In the month of May of the same year, 123 ounces of eggs were ordered out from France from the following firms —

(a) Laurent de L'arbusset	60 ozs
(b) Leon Delonca	69 „
(c) M Galford	3 „

but only 74 ozs were received. The rest were interrupted at Marseilles on account of War and perished there. These 74 ozs were taken to Chail Hill station for hybernation during the winter months and fared well. 5 ozs out of these perished and the remaining 69 ounces were reared in the spring 1915 as under —

10 ounces by the Director of Sericulture at his residential quarters
 44 ounces by the Zamindars in the Pail Tahsil
 55 ounces by the Zamindars in the Sirhind Tahsil

Total yield from these 69 ounces was 18 maunds of "green" cocoons giving an average of 10 seers 7 chittacks per ounce of eggs. Four of the rearers obtained exceptionally good results. Their average yield of cocoons per ounce was over a maund which is very encouraging indeed. The results of the majority of the rest were poor which was naturally due to the fact that they were not yet experienced enough in the rearing operation as also to insufficient attention and care on their part.

The produce of cocoons of 1914 (16 seers) was got reeled at the Salvation Army's institution at Aligarh and 3 seers of raw silk were obtained therefrom giving an average of 20 per cent.

During the current year, 210 ounces of eggs have been distributed, 10½ ounces of which have been distributed to village schools and it is hoped that results with the outturn of cocoons will be better this year. This year's seed has been distributed to 532 rearers which represent about 140 families.

Two reels have now been put up at Patiala and three reelers have been properly trained. Their number will be increased as work expands.

Patiala State provides various grades of climate suitable for sericulture and it is expected that with the exception of the District of Narnaul and portions of Bhatinda the entire State will be found suitable for silk rearing

There are at present 38,574 trees in the State in 725 villages but there are only 210 villages which possess 50 trees or more in each. Steps are being taken to establish State nurseries and encourage mulberry plantation both by the State and through private agency

It is a matter of great satisfaction that within the territories of the State the Chail Hill station provides quite a good place for the hibernation of seed. A proper hibernation house will be built there in course of time

The hilly tract of the State which extends from Kalka to Chail and Kufie could form a very good nursing ground for mulberry. There are no mulberry trees existing in this tract at present but it is hoped that early start will be made for the propagation and extension of mulberry trees over this part of the State as well. So that in course of time the State will be in a position to place a decent outturn of silk in the Indian and European markets

Some of the raw silk produced experimentally during the last two years by the Sericulture Department was sent to Europe for test and report. Attached herewith are copies of the reports received, showing the quality and worth of the silk produced at Patiala

DAYA KISHAN KAUL

The 11th September 1916

THE SILK ASSOCIATION OF GREAT BRITAIN AND IRELAND INCORPORATED

3/4, NEWGATE STREET, E C ,

The 15th February 1916

Since writing you to say that the small parcel of raw silk had arrived, I have had the skeins distributed to various quarters for examination and report, and I am glad to tell you the result, in each case, is most satisfactory. I enclose extracts from the reports sent in, also certificates from the Bradford Conditioning House, which will probably be useful for you to hold. Two of the skeins have been thrown into three threads tram, these I am going to have boiled off and woven into a cloth

The outstanding merits of the silk are, regularity in size, good elasticity and strength. Its chief defect is that it is nibby, which entails more than the average waste in winding, this is a defect which you will undoubtedly be able to overcome

REPORT No 1

With further reference to your favour of the 27th ultimo, we have now carefully tested the sample of raw silk which you sent on to us, and consider it a very good quality indeed. In order to assist you all possible we have also made a comparative test of 10/12 Denier Japan Filature, and the sample of silk you have sent gives better results than the Japan silk, the particular point in its favour being the great regularity in size, even in comparison with Japan Filature which is always considered quite satisfactory from this point of view. We found the Indian product to be an excellent winder and the thread was very free from Slubs, etc

Below we give you the results of the two tests in detail, and trust same will be of service to you

We consider the silk quite as regular and strong for its size as Exquis Italian

The elasticity of both threads give the same average of $3\frac{1}{4}$ " on six tests, and each test was practically the same

REPORT No 2

I can now report on the skein you sent me, no test for evenness would represent the bulk satisfactorily, without taken from a larger number of skeins Still, the test from the two skeins submitted gives a good result I send you with it a small skein marked AN I, which you may like to compare with it, and it gives a very similar test, and is part of a run we have just completed throwing We have specialised in this class of silk for some years

The percentage marks resulting from the 4 tests are as follows —

Test.	Per cent	Remarks
Cleanliness . . .	91	Very good
Winding	93	Over average
Tenacity	71	Slightly under average
Elasticity	79	Very good
Titre		Not stated
Conclusion		A generally satisfactory test

REPORT No 3

We have yours of 27th instant, and have pleasure in reporting as under-noted on the two hanks of Indian silk, which we return herewith

In appearance it is good and looks a nice silk—for strength it is fairly good, and it is also fairly clean. As to the evenliness—it contains a number of very fine ends, which would be fatal to the silk being used as warp—there are also some coarse threads.

REPORT No 4

The enclosed skeins of three threads tram, are the product of the two skeins Bengal on which you wished a report.

The silk was lightly washed, and wound very well at an easy speed.

The tenacity and elasticity test was on the *Single* thread, and is very good.

The size in three threads tram is $2\frac{1}{2}$ drams to 1,000 yards.

SERICULTURE OPERATIONS IN KALSIA STATE

1912-13 —The operations were started for the first time this year as an experiment with 4 ounces of silkworms-seeds, which lasted upto 1st May 1913. The total expenditure has been Rs 123 with an income of Rs 45, price of 20 seers of cocoons produce. The seeds were very kindly supplied by the Director of Agriculture, Punjab.

1913-14 —This year the rearing of silk worms was started with 7 ounces of seeds. The total expenditure has been Rs 49 with an income of Rs 92 by the sale of cocoons weighing one maund. Mr W S Hamilton, I C S, Director of Agriculture, Punjab, paid a visit and saw the work, and under his orders the Inspector, M Jala-Uddin, made frequent inspections and gave good advices, Mr Madan Mohan Lal, Entomologist, also visited the work.

1914-15 —This year the rearing of silkworms was started with 7 ounces of seeds. The total expenditure was Rs 49, and one maund of dry cocoons were sold for Rs 103-12. Mr Madan Mohan Lal, B Sc, Assistant Professor of Entomology, Lyallpur, visited Chachrauli, capital of State, on 25th January 1915, and gave his instructions on the rearing of silkworms. According to his advice the seeds were distributed this year among the villagers of Chachrauli and Bassi Tahsils for rearing under the supervision of Zaildars, Lambardars, and Lala Ram Sarup, Darogha, which was very satisfactory.

1915-16 —This year the rearing of silk worms was started with 4 ounces of silkworm seeds, but owing to the negligence of the rearers of the Chachrauli Tahsil 3 ounces were wasted altogether, and only one ounce reared in the Bassi Tahsil produced only 13 seers of cocoons, valuing Rs 28. The expenditure incurred was Rs 4 only.

1916-17 —Indent of 4 ounces of silk-worm seeds, has been sent for the next year 1916-17.

FOREST DEPARTMENT

Changa Manga, 1884 —Forest Department tried operations at Changa Manga in 1884 and 1885, with Japanese worms and got cocoons. In 1886, worms died to 75 per cent from intense heat.

	Rs
The expenditure was	2,951
The receipts	821
	—
Loss	2,090
	—

Extract from the Annual Report of the Silk Centres of the Salvation Army in India and Ceylon, 1913-14, by F de L Booth Tucker.

Changa Manga

The results for the season of 1914 are just to hand

* * * * *

The crop was making excellent progress and promised to be a record one, when a sudden heat spell struck the district and for several days the temperature rose to 100 and upwards, just as the worms were commencing to spin. Those which had already spun produced cocoons equal to the best European samples. But the rest suffered severely, a large proportion of worms dying and the rest producing what might be described, as an eight anna crop of cocoons.

NORTH-WEST FRONTIER PROVINCE

Copy of a letter from Rai Sahib Prabh Dyal, Bar-at-Law, Peshawar, to the Revenue Commissioner, North-West Frontier Province, Peshawar

With reference to your letter No 395, dated the 21st December 1915, we beg to say that we worked Sericulture in Hazara for three years and had to give up at last. As far as rearing silkworm was concerned, it was quite a success and we were able to get as good cocoons as they sent us every year from France and Italy.

2 We had started silk reeling in Haripur which was very successful and we had trained 6 boys of Haripur who were able to do the reeling very nicely. The difficulties that we met in the way of carrying on the work were as follows:—

- (a) We could not find any market for the silk so produced in India. Wherever we sent the silk, they said it was too fine and superior and could not be used in India. We could sell the second quality only in India in Benares and not the best one, which we had to send to England after three years' collection. The net loss to us was about Rs 3,000 during the three years.
- (b) The causes of this loss were that we had to hire houses in Haripur, which added to the cost of rearing. Ordinarily when Zamindars do the rearing they have not to pay anything in the shape of rent and use their own rooms and even if need be, they could get rooms in the villages at a very low rent.
- (c) We had to engage coolies to bring mulberry leaves from the roadside and paid them annas 4 and annas 5 per day, but as the season advanced and cutting of the crops were started, these coolies would desert the work and go to harvesting wheat where they could earn as much as Re 1 per day, while we could not pay more than annas 8 per day.
- (d) The material for making shelves for the worms was also expensive, but this could be easily remedied as ordinary bamboo poles could be imported.

We were able to carry on the work with the permission of the Public Works Department authorities, who very kindly permitted us to use the mulberry leaves from the roadside and without their help we would not have been able to do anything in the matter. We tried to grow the worms in villages also, in the hope that the Zamindar would take up the cocoon growing and we could carry on the reeling but the Zamindars did not take up the idea. Had they taken up the industry we would have kept up the Model Farm in Haripur and would have supplied the seed to all who would have taken to silk rearing.

I requested the Deputy Commissioner to kindly ask the Patwaris and the Lambardars to advocate silk rearing, but nothing could be done without the help of Government and we had to give up the venture.

BALUCHISTAN

Copy of a letter No 1910, dated Mastung, the 6th October 1910, from the Political Agent, Kalat, to the First Assistant to the Hon'ble the Agent to the Governor General in Baluchistan

I have the honour to submit the following report in connection with the sericulture operations conducted by the Kalat State

2 I attach a statement at Appendix A, which gives in tabular form a brief history of the sericulture operations year by year from 1904 when they were first introduced up to the close of the operations of the current year

3 It will be observed that the total cost of the operations and the upkeep of the industry has been Rs 57,630 during the above period while the income derived therefrom comes to only Rs 10,595 which shows a total loss to the State of Rs 47,035 within the period of seven years. Against this may be credited the present value of the factory and plant which is estimated at Rs 11,500. The industry has never been self supporting nor in any one year has the income received been sufficient to cover the cost of upkeep and working expenses

4 This failure which is much to be regretted may be attributed to the following —

(1) The exorbitant rate demanded for mulberry leaf which rose from annas 6 per maund in 1906 to Re 1 in 1910. In this connection I would point out as has already been mentioned in the Kalat Administration Reports that the mulberry is not only a valuable marketable commodity among the Brahuis of Mastung but is also often their only means of existence (in a dried form) during the winter. The process of leaf picking—as it at present exists—involves a certain amount of loss in fruit and consequently the Brahuis are most unwilling even to sell their leaves. Every year since the scope of the operations was enlarged, we have had the greatest difficulty to obtain the supply necessary to feed the worms. Brahuis have been known to tie Korans on their trees to secure exemption from having to give the leaf even at the exorbitant rate mentioned above

(2) The want of enterprise on the part of the local inhabitants who have steadily refused to take any interest in the scheme or to be persuaded to introduce it into their homes as a cottage industry, and this in spite of the fact that every effort has been made to make the operations both attractive and remunerative locally

5 At the beginning of the present year the supervision of the operations which had been in the hands of the Assistant Political Agent for the past six years, during which period all concerned had been carefully trained in their respective duties, was handed over to the State officials and the Political Adviser to His Highness the Khan has now reported that the estimated loss for this year will amount to Rs 4,316 exclusive of the cost of mulberry leaf which he estimates at Rs 4,051

It is unfortunate that this year—the first, under his supervision,—disease which had hitherto never seriously attacked the worms, broke out in the factory at the end of the operations

The Political Adviser asks on behalf of His Highness the Khan that further operations may be discontinued when the results have been proved to be “so ruinous and unprofitable” to the State

6 I am reluctantly compelled to agree with him and to recommend that the industry should be abandoned at any rate for some years

I would suggest that when the many thousands of mulberry trees which are reported by the Political Adviser to have been planted, have grown up the operations should be recommended say in four or five years' time. By that time the industry with its own plantations of mulberry bushes instead of trees ought to be independent of local owners for its leaf supply. I am, however, very doubtful even if the leaf be obtained gratis, whether any large profits could ever be expected as long as the inhabitants show no interests in the industry and as long as it is not taken up by them as a cottage industry

APPENDIX A

Statement showing the output annually and the cost of the upkeep in each year of the Mastung Silk Industry

Year	OUTPUT					Results
	Quantity of seed purchased.	Total yield of cocoons weight.	Raw silk obtained weight.	Amount realised by sale of silk	Cost of upkeep	
1904	4 oz	40 lbs	13 lbs	Rs 71	Rs	The experiment was conducted in the Mastung Thana by a clerk of Political Agent's office under the supervision of Political Agent and a portion of the worms was made over to the Political Adviser who placed them in the out offices of the Mastung Miri. No special establishment was entertained and nothing was paid for the mulberry leaf as the small amount required was obtained from His Highness the Khan's gardens. The reeling was done on a machine belonging to Mr Rogers of Quetta and under the supervision of a Kashmir expert temporarily employed by him. The result was satisfactory.
1905	10 oz 238 lbs.	No reeling was done during this year			323	An experiment with $\frac{1}{2}$ oz of seed was made at Mach in the Bolan Pass but it was not successful as all the eggs hatched out prematurely. The remaining quantity of seed was utilised in the Mastung Thana and Miri towards the end of the operations. Disease broke out among the worms owing to insufficient feeding. The yield worked out to 23 pounds of cocoons from one ounce of seed as compared with general continental average of $31\frac{1}{4}$ lbs of cocoons per ounce of seed. Major Showers was of opinion that the success of the operations was so encouraging that it was determined to considerably extend the scope of the season's operations.
1906	240 oz.	2,080 lbs	339 lbs. 14 oz.	2,462	14,000*	Major Showers anticipated that 1,040 lbs or 50 per cent of raw silk would be obtained from 2,080 lbs of cocoons but the actual yield of silk was only 339 lbs. The yield eventually worked out to $5\frac{1}{4}$ lbs. of silk per 100 lbs of green cocoons and this result was considered to be sufficient to justify continuance of the operations. The supply of mulberry leaf had to be purchased. The price demanded and which was paid was 6 annas per maund.

* Includes cost of factory building

Statement showing the output annually and the cost of the upkeep in each year of the Mastung Silk Industry—concl'd

Year	OUTPUT					Results
	Quantity of seed purchased	Total yield of cocoons weight	Raw silk obtained weight	Amount realised by sale of silk	Cost of upkeep	
1907	143 oz.	2,090 lbs	361 lbs 14 oz.	Rs.	Rs 13,060	The result was not satisfactory and it was represented to H A G G that from a financial point of view the enterprise was at present being run at a loss to the State. This was mainly due to the necessity of our having to buy the leaf supply at exorbitant rates and pay heavily for the labour of rearing the worms. The price for leaves had to be raised from 6 annas to 10 annas per maund.
1908	147 oz. 4 410 grammes	3,797 lbs	228 lbs	3,253	12,000	A box of 30 grammes of seed produced 13 seers of green cocoons if compared with 23½ seers from one box of the last year. The results were exceedingly unsatisfactory and it was reported in the Kalat Agency Administration Report that the industry had been again this year run at a loss to the State and that more than Rs 40,000 had already been spent on it. It was also added that in view of the impossibility to run it as a cottage industry owing to the opposition of the local inhabitants and their refusal to give the leaf at anything but a prohibitive price, it would be necessary to consider seriously the advisability of discontinuing the operations. The price of leaves had again to be further raised from 10 annas to Re 1 per maund.
1909	70 oz.	4,185 lbs	320 lbs	Cost not yet received from Quetta City but estimated Rs 2,880	7,000	The rate of Re 1 per maund for the leaf introduced last year had to be continued during the year. The result though more satisfactory than that of last year was a loss to the State from a business point of view. Up to this time the supervision of the industry had been in the hands of the Assistant Political Agent, Kalat.
1910	150 oz.	1,010 lbs	2,281 lbs (approximately)	2,000	11,247	The industry having been supervised for six years by the Assistant Political Agent during which period all concerned had been carefully trained in their respective duties, it was decided to transfer the supervision of the operations to the Political Adviser of His Highness the Khan. The price for the leaves remained unchanged and the results were exceedingly bad. This was attributed by the Political Adviser to the sudden outbreak of disease among the worms at the end of the operations.
TOTAL	10,595	57,630	

Copy of a letter from Major H B St JOHN, C I E , I A , Political Agent, Quetta-Pishin, No 1603, dated the 10th May 1916

* * * * *

2 It appears from the records of my office that the question was taken up during the year 1903, and Mr Rogers, the then Manager of the Murree Brewery Company, Limited, Quetta, took a great interest in starting an industry in this District. His efforts met with partial success as will be seen from the copy of the attached correspondence, but on his departure from Baluchistan, no one else came forward to carry on the work and the industry practically came to a standstill

Extract from a demi-official letter, dated the 26th October 1904, from Mr J R. D Rogers, to the Hon'ble Colonel Yate, C S I , C M G , Agent to the Governor General in Baluchistan

* * * * *

1 With reference to Sericulture in Baluchistan, I have the honour to state that I continued my last year's experiments this summer, but on a very much larger scale

2 I rented several houses in the village of Kasi and Kirani for rearing silk worms and employed over 100 men and boys from these and adjacent villages, all of whom were more or less taught how to rear worms

3 I regret to state, however, owing to the ignorance and indifference of the Maliks, I had the greatest possible difficulty in obtaining sufficient mulberry leaf, what I did get I had to pay exorbitant prices for

4 I even had to get leaf from as far off as Mach by mail train daily, but owing to the heat and railway journey the leaf on the way fermented and was useless. Had the Maliks given me sufficient leaf, my experiment would have been a great success, but owing to their obstinacy and refusing to give me leaf (which they had in abundance) I unfortunately lost $\frac{3}{4}$ of my crop, as the worms were starved and so became diseased and died, in consequence instead of the experiment being a financial success, it was a dead loss

5 However, I have the satisfaction of knowing that I have managed to introduce Sericulture into Baluchistan and Kalat

6 The people now have some idea as to what silk is and how the worms should be reared, a number have even expressed a wish to try and rear worms themselves next year. I have promised them eggs and every help

7 So as to further teach the people of the country I erected 2 reeling machines, the parts having been imported from France. I did all I could to induce the people from the highest to the lowest to come and see the reeling of silk and personally explained every thing in detail

8 I am sure Sericulture will soon spread throughout Baluchistan and Kalat once the Maliks and the people realize what a profitable industry it is, if seriously taken up. The great drawback at present is the want of leaf though the villagers themselves have more than enough to make a start on

9 If the Maliks would only interest themselves a bit and try to induce the people to take up an industry, which would be an additional source of profit with little trouble to them, Sericulture would flourish *next year*

10 I have planted over 1,000 mulberry trees this year, all are doing exceptionally well. Next year I hope to be able to plant out a very much larger number, if I can only procure the necessary land

Note regarding experiments made by Mr Rogers in Sericulture, etc (This forms an enclosure to letter No 1603, dated the 10th May 1916, from the Political Agent, Quetta-Pishin)

Mr Rogers, who has taken great interest in starting Sericulture in Baluchistan, has recently made a report to the Local Government regarding

his operations during the past summer, which indicates that, in spite of some difficulties he had to encounter in the way of obtaining mulberry leaf on which to feed the worms, his experiments have been fairly successful. Several houses were rented by him in the villages of Kası and Kiranı near Quetta for rearing silk worms and some 100 men and boys from these and adjacent villages were employed, all of whom more or less were taught how to rear worms. The ignorance of the Malikhs and people and the suspicion with which they are prone to regard any new departure prevented the experiments from proving as successful as would otherwise have been the case as it was difficult to induce them to give sufficient mulberry leaf, which they had in abundance, even at high prices. The importation of mulberry leaf, from Mach by rail was tried, but owing to the heat of the railway journey the leaf fermented and became useless. The consequence was that a considerable proportion of the crop failed as the worms being starved for want of leaf became diseased and died. However, a fair amount of silk of first rate quality was produced and was exhibited at the Horticultural Show and it is hoped that the people will soon realize the benefit of rearing worms and take to themselves specially as Mr Rogers has promised them eggs and every help. Mr Rogers has also erected two reeling machines, which he imported from France. People were invited to come and see the reeling of silk and the process was explained to them in detail.

The great drawback at present is the insufficiency of mulberry leaf. With a view to increasing it, Mr Rogers has himself planted over 1,000 mulberry trees, which are doing well and orders have been issued by the Revenue Commissioner which will, it is hoped lead to the increased planting of mulberries in the various districts. Mr Rogers proposes to visit various parts of Baluchistan, in order to show the people the samples of silks, which were recently exhibited at the Horse Show at Quetta, to explain what excellent qualities can be produced in Baluchistan, and to see what can be done in the way of inducing the Malikhs and people to start sericulture for themselves. Mr Rogers has also experimented with success in the cultivation of tea, tobacco, castor oil and gram and he proposes to experiment with cotton from seed to be obtained from America, Australia and Egypt.

C ARCHER,

*Revenue Commissioner
in Baluchistan*

INDORE

Enclosure to Central India Agency letter, No 967-D, dated the 28th April 1916,
to the Imperial Silk Specialist

Note on the Silk Industry Department

With a view to provide the cultivators with means to make up the loss they sustained in the stoppage of opium cultivation, His Highness the Maharaja Holkar had opened the Silk Industry Department at Indore, in the year 1912, and ordered the purchase of cocoons through Commissioner Booth Tucker of the Salvation Army, Simla. Services of an expert were then secured, one officer and weavers were sent to Moradabad for training, cuttings of mulberry and necessary machines were ordered out from Bangalore and Ludhiana, respectively, and every effort was made to make a good start.

The following branches are at present worked in the Institute —

- (1) Rearing of worms
- (2) Reeling and spinning
- (3) Dying and bleaching
- (4) Twisting and weaving
- (5) Central Nursery
- (6) Museum and Library.

BOMBAY

1823, the Collector of Dharwar, introduced mulberry worms from Mysore and grew silk in the jail and got ryots to do it. This went on locally till in 1842, 400 lbs of inferior silk were made.

In 1880, a rearer was still doing it, presumably for local use.

The water is too deep for irrigation to pay. (Geoghegan)

In Khandesh, the Collector commenced in 1826. In 1831 the silk was classed as equal to 3rd or 4th class Canton. In 1837, Mutti inspected it and found trees grew well, and worms were well, but the whole was in the charge of three peons, who were entirely ignorant. "From first to last no one, who had ever had any practical experience in silk culture had any share in the management." In 1838 it ceased. (Geoghegan)

In 1831, Dr Graham was growing mulberry at Ahmadnagar. He grew *M. indica* to start and later *M. alba*. He grew boro-polo apparently, but this is doubtful as he had worms in November. Dr Graham went on leave, in 1838, others had it and in 1845, the whole stopped. The silk fetched Rs 12 a seer. (Geoghegan)

Failure probably due to irrigation being required and to ignorance.

Signor Mutti worked in Poona, Bombay, etc., from 1831 to 1848. Much mulberry was planted and he grew Bengal multivoltines. He distributed the worms as they hatched. The silk cocoons yielded at 9 kahans to 1 seer silk. Trees were planted at Poona, Ahmadnagar, Dhulia, Nasik, Kathiawar, Kaira, Ahmadabad, Bassein, Mahim, Dharwar, etc., and worms reared.

The failure ultimately seems to have been due to poor leaf, partly owing to 'standards,' no fresh seed, and no steady continuity in money supply. (Geoghegan)

From 1865 to 1874, experiments were continued at Dharwar they showed that mulberry grew well and that silk could be produced, but nothing further happened. The following is of interest —

*Extract from the Proceedings of the Poona Agricultural Conference
held on 2nd October 1909*

Mr A. M. Bidkar (Belgaum). He can have half an acre of land or can use his backyard for growing mulberry trees, which would enable him to rear some silk-worms and thus gain a good income from it. From enquiries that I have made and from what I have read I have learnt that places where the thermometer does not rise over 90 or go below 60 in shade is a fit place for sericulture and such places can be found in and near about Belgaum. I have come to know from old persons that silkworms were reared in Belgaum some 70 years ago and many mulberry trees were seen by me in the backyards of several houses. Now a trace here and there of these trees can also be seen here. No causes why this industry was discontinued here can be known. I have seen about four years ago some silkworms were reared by a man and he used to collect mulberry leaves from trees in the backyard of several persons. It is plain at all events that the climate of Belgaum and places on the ghats to the West and South of Belgaum is suited for sericulture.

BARODA.

In 1905-06, the Director of Agriculture, visited Kashmir, to see the industry there and N. G. Mukherji, visited Baroda and advised, his report was very detailed and should be consulted.

The Administration reports from 1905-06 to 1913-14, give a record of subsequent progress. Two schools were started in 1905-06, five crops of silk were got and a special officer was put on duty at Navsari to spread the industry. There were 25 students at the Songad School next year, and this school was increased in 1907-08. There were 70 students at the Vyara School.

in 1908-09 Crops of worms had been taken continuously and mulberry planted Yet in 1908-09, the report says that only three persons were doing mulberry silk as an industry and 82 doing the newly introduced eri Next year the two schools were moved away, one to Baroda, the other to Navsari, the latter was abandoned in 1913-14, both continued taking crops of silk but eri was the only silk the people took any interest in

The Baroda station has continued to rear eri and mulberry with an occasional failure due to heat The reasons ascribed for the failure of mulberry are the cost of irrigation of mulberry, the objection to killing the cocoons, the failure of eri is due to the loss of the market for cocoons, the Bombay Mill having ceased to buy cocoons Something may be ascribed to the method adopted which was the curious one of teaching sericulture before anyone knew how to make sericulture profitable in Baroda Too much confidence was placed in N G Mukherji's proposals, which were afterwards found to be ill adapted to the climatic conditions of the State.

If sericulture is ever to be developed it will only be by beginning at the right end and growing silk profitably, with expert advice, before teaching sericulture

COORG

From the Deputy Director Land Records and Agriculture, Mercara, Coorg

Dated the 19th July 1916

I have the honour to bring to your notice that the eggs of silkworms (Multivoltine) which you kindly supplied me about 18 months ago have done exceedingly well They were not at all subject to any disease, and continued to breed regularly completing their course in about five weeks time, or less

As regards the cocoons, am sending you a few specimens But the Imperial Silk Expert Mr Maxwell Lefroy was of opinion that the quality of silk was inferior to that raised in Mysore and on his advice I obtained eggs from the Chennapatna Farm in Mysore These were, however, most disappointing, as they were very delicate and suffered much from the disease known as flacherie I don't think that their cocoons are even as good as the Pusa ones And I am sending you also the specimens of the Mysore kind

It is possible that your variety has deteriorated and I shall feel very thankful if you will kindly send me a fresh supply for about 80 trays, for which I shall gladly pay Please also do me the favour to advise me whether you would advise me to cross breed and on what lines?

MADRAS

1790-98 Dr Anderson stimulated Government and large efforts were made to introduce the silk industry in Madras It was abandoned finally after spending £20,000, as the cost of cultivation, irrigation, etc, was too high

1794-96 Filature was established at Vallavedu and trees were planted 460 lbs of filature silk and 550 lbs of waste had been made at the filature at the cost of Rs 78,736

1797, January to March 169 lbs of silk, and 135 lbs of waste silk had been produced

The whole failed as natives would not take to it and with paid labour it cost too much

In 1870, silk cultivation was actually being carried on in Coimbatore and Salem, also in Cuddapah, North Arcot Tinnevely, and South Canara

See reports of industry in Salem yielding Rs 27-4-0 profit per acre, and of Tinnevely yielding Rs 75 per 62 acre (Geoghegan)

A series of experiments were made in 1883 with seed from Kashmir, from Lister and Co, and from China, at Saidapet, at Coimbatore and Rajahmundry and at Yercaud in Salem. Results at Saidapet were indefinite, at the other places, they were spoilt by the eggs having largely hatched on arrival, at Coimbatore of Lister's eggs 5,230 worms hatched and all spun, they reeled at a rate equivalent to 4 lbs raw silk per ounce of eggs, the Kashmir eggs gave worms many of which died of flacherie, the cocoons reeled at the rate of 4 lbs 8 oz raw silk per ounce of seed. At Yercaud, the worms that hatched apparently did well.

It will be evident that not much could be learned from these trials, done as they were in this curious manner, the same trials were made at Berhampur and Rampur Bauleah Jails, and at Saharanpur, the seed used at Chhindwara (see page 137) was from this source and there alone definite results were obtained.

TRAVANCORE

Extract from report of Travancore, Department of Agriculture for 1914-15 X *Sericulture*

The silk farm at Trivandrum, is intended solely for experimental purposes. Owing to the limited grant sanctioned for the farm and the absence of sufficient accommodation and appliances, silkworm culture cannot be undertaken on a commercial scale. Besides for the conduct of experiments, the farm serves for the distribution of mulberry cuttings and silkworm eggs to the public.

In previous years equal attention was bestowed upon the cultivation of eri and mulberry silkworms. But during the year under report more attention was paid to the latter than to the former, because of the practical difficulty experienced in conducting both the operations successfully in the limited accommodation available in the farm. Any how, two small crops of eri silkworms were raised in the earlier part of the year and five crops of mulberry silkworms throughout the year. The latter yielded 300 lbs of green cocoons. A portion of this was reeled and woven into cloth, which was sold at Rs 2 per yard, and the balance of the cocoons was sold to the Salvation Army's Silk Farm at Bangalore at 12 annas per lb of dried cocoons.

The experiments conducted so far in the silk farm leave no room for doubt about the feasibility of carrying on silkworm culture in Travancore, in about six months of the year, when there is neither severe drought nor heavy rain, both of these conditions being unfavourable for the growth of silkworms. What remains to be done is to persuade the people to take interest in this new industry. This is now being done by delivering popular lectures and distributing leaflets on the subject and by supplying mulberry cuttings and silkworm eggs free to the people. During the year under report 20 bundles of cuttings were distributed to 160 persons through the Local Salvation Army Officers, 30 bundles were supplied to one Mr Thomas of Vandeperiyar and some 10 bundles were distributed to a few people in and about Trivandrum.

The mulberry plantations, which the Department opened at Tiruvella and Oachaira continued to make satisfactory progress and a new plantation was also opened at Kaipattur. Cultivation of silkworms will be undertaken at all these places in due course. They are mainly intended to serve as centres for the distribution of Mulberry cuttings and silkworm seeds.

A new move towards the popularisation of the silk industry in Travancore has been decided upon and will be made in the course of the current year. It is the starting of a sericultural school at Trivandrum under the control of the Salvation Army, for which the army will receive a monthly grant of Rs 50 from the Department. As at present arranged, the school will be opened in May 1916. To begin with the school will contain accommodation for 12 boys only, but in the course of three years accommodation will be provided for 50 boys.

been reared on a large scale since September 1915, and on a very large scale since March 1916, and the 46th generation has given cocoons which still continue to be superior to the Nistari. From this six groups each consisting of hundreds of families, have been selected and are being reared separately.

A very rigorous selection is being made not only with regard to the cocoons but also with regard to the moths and layings. The best layings only are kept from moths which have lived many days after eggs hatch. I have found that selection for longevity alone gives very good results in making the race vigorous and immune to disease. Many of the moths live over twenty days, some about twenty-four days and one male moth lived nearly two months.

A black race of worms of a very dark grey colour has been obtained from five black mutations which appeared in family 303 of the 37th generation. The 37th generation was the first to be reared on a very large scale since the cross was started in January 1911. As the worms owing to their dark colour are almost invisible among the mulberry leaves I thought the native rearers would probably have nothing to do with them. However some rearers who have seen them say they would be much valued in the silk districts. Their dark colour may be of some use as the silkworm fly would have difficulty in finding them out. In their dark velvety markings they much resemble the larvæ of the wild silkworm *Theophila huttoni*, and are probably a throw back to some ancestral type and are interesting on this account.

Another mutation also appeared among the worms in the 43rd generation, these were spotted worms. There were only about six or seven at first but I now have quite a number. All the worms usually have four markings on two segments but these have markings on each segment and so in their markings much resemble the larvæ of *Theophila huttoni*.

In my Ital-Jap and Nistari cross I have found, that, after the direct influence of the fresh cross seemed to have disappeared, every third generation produced the best cocoons, for the cocoons of the 6th generation, 9th, 12th, and 15th generations were much superior to those of the intervening generations. Even those of the 12th generation serposited during the rains in July, were much better than those of the 10th generation (April) and the 14th generation serposited in October 1916), every third generation has produced the best cocoons. As the rayats in India grow about three or four crops of cocoons a year (only rearing a few to keep the breed alive when they are short of leaf) it would be to their advantage to arrange that the crops reared are of every third generation.

The cocoons obtained from this multivoltine race are much superior to the Nistari, those of the 9th generation were valued at about 9½ francs per kilo in the Milan Market, which is close up to the price of good Italian cocoons, and the cocoons of the 13th generation were valued at about 7 francs per kilo.

In the 17th generation this hybrid race was recrossed with Nistari and in the 34th generation with family No. 303 of my father's accidental Multivoltine race of the Italian-Japanese hybrid. After the first rearing on a large scale in September 1915 the race was divided into various groups —

- 1 303, the family in which the black worms appeared
- 2 7(a) and 4(b) sets with particularly good textured cocoons
- 3 "One" and "two laying" sets, which were from the 303 set
- 4 Black female set which has both black and white worms
- 5 108 and 4 and 5 recrossed with Mysore in the 36th generation
- 6 My father's race of Italian-Japanese Hybrid which was recrossed with Nistari in the 35th generation. This race was also started in January 1911
- 7 329 set from a female of my father's race which lived twenty-four days

The 7th September 1916,

M. L. CLEGHORN.

Annual report on Scientific work in connection with silk for the year ending 30th June 1916, by Miss M. L. Cleghorn, F.L.S., F.E.S.

In April 1916 a grant of Rs 10,000 was sanctioned by Government for the extension of my silk experiments and research.

My silk laboratory has been much enlarged, the three control rearing houses for village rearers completed, and a new mulberry plantation of about 8 bighas of land in Hastings House, which was very kindly given by the Honorable Mr. W. W. Hornell, Director of Public Instruction, has been dug up and planted out with about 400 thin sweet-leaved male mulberry, and part of the plot is being prepared for the cultivation of bush mulberry according to indigenous methods.

Mr H. Maxwell-Lefroy, Imperial Silk Expert, who was deputed by the Secretary of State to report on the Silk Industry, visited my Sericultural Laboratory and expressed much satisfaction at the way in which the work was being carried out. Mr Lefroy suggested that a comparative trial should be made between my hybrid race and the indigenous Nistari and Desi. So a large education of the 41st generation of my multivoltine hybrid race, started in January 1911, was reared and a kahan of seed cocoons of this generation was forwarded to Mr. J. de Minvielle, Manager of Messrs. Anderson Wright & Co's Filature Concern at Ramnugger. The trial cocoons reared at Ramnugger were of the 42nd generation of my cross, and the worms from start to finish gave no trouble in spite of very hot weather, and were healthy throughout the education. These cocoons gave about 36 per cent better produce than the control Nistari and Desi which were reared at the same time, and went 12 kahans 12 puns to the seer of silk, while the control Chotapolu went 18 kahans 10 puns, and the control Nistari 17 kahans 14 puns to the seer of silk.

This hybrid race between the Italian-Japanese and Nistari, which was started in January 1911, has been reared on a very large scale since September 1915. From this six groups each consisting of hundreds of families have been selected and are being reared separately.

A very rigorous selection is being made not only with regard to the cocoons but also with regard to the moths and layings. The best layings only are kept from moths which have lived many days after eggs hatch. I have found that selection for longevity alone gives very good results in making the race vigorous and immune to disease. Many of the moths live over twenty days, some about twenty-four days and one male moth lived nearly two months.

A black race of worms of a very dark grey colour has been obtained from five black mutations which appeared in family 303 of the 37th generation. The 37th generation was the first to be reared on a very large scale since the cross was started in January 1911. The worms owing to their dark colour are almost invisible among the mulberry leaves and on this account the native rearers would probably have nothing to do with them. However their dark colour may be of some use as the silkworms would have difficulty in finding them out. In their dark velvety markings they much resemble the larvae of the wild silk worm *Trospila huttoni*, and probably a throw back to some ancestral type and are interesting on this account.

I received a letter from Dr. W. S. Sutherland of the Scottish Universities, Madras, Kalampong, asking for advice regarding silkworms. I gave him all the necessary assistance regarding them and abstract him fifteen layings of the 44th generation of my hybrid race. They were reared at Kalampong, where a large loss during the education and the cocoons produced were large and fine and of good texture. Dr. Sutherland has also planted out in a special plot 250 thin sweet-leaved male mulberry plants which I sent him as I have found that the worms fed on this variety give the best results. It is hoped that when there is a crop of this mulberry that at least three crops a year of my cocoons may be obtained at Kalampong for rearing in Bengal climates.

M. L. CLEGHORN.

The Brown Disease of the Berry.

The disease is caused by the presence of *Dactylothea* sp. *Dactylothea* sp. for *Dactylothea* sp. *Dactylothea* sp. on the leaves of Mulberry. The leaves of the infected plants

become hard and compact. The leaves first become deep coppery green, turn pale yellow and either drop off or remain on the plants. They, however, become very crisp and are lacking in nutritive factors. In course of time, as more nymphs hatch out and mature on the infested plants, the plants lose their freshness and vigour and appear pale and sickly. The field presents a peculiar appearance, the individual plants having few leaves but with prominent gnarled heads.

In some places where the whitish leaf-fungus [*Phyllactinea Corylea* (Pers) Karst] is present leaf denudation is more rapid and prominent. In a case under observation it was found that a few potted plants of *Morus Sp* remained immune from the attacks of the leaf-fungus for over three months, but as soon as the plants became infested with *Dactylopius Sp* the appearance of the fungus on the leaves was very rapid and prominent. The first signs of the leaf-fungus were detected a fortnight after the plants were inoculated with a few nymphs of *Dactylopius Sp* and a month later, there were left only a few leaves on the lower portion of the stem. With the presence of the leaf-fungus, the infested leaves turn pale yellow, assume a brownish colour, dry up and fall down. The plant subsequently presents a weak, straggling growth.

The female is light castaneous in colour, flat, somewhat longer than broad and is covered with a thin whitish meal, with a pair of stout, bent, caudal setae. After laying eggs she is 1.32 mm long, 1.29 mm broad. The ovisac is pure white, at one end of which the female remains shrivelled up. The ovisac is full of small, cylindrical, pinkish eggs, each egg being 36 μ m long, 21 μ m broad, one end being suffused with pale brown. The eggs are laid compactly within the ovisac. A week after, the eggs hatch out into small, flat, pinkish nymphs which wander about slowly on the plant in search of suitable plant to fix themselves on. Each nymph is 42 μ m long, antennae nearly as long as the caudal setae.

After wandering about, the nymph prefers to fix itself in the axil of a leaf, and a week after, its presence makes itself prominent by the flattening out of the apical stem below the top shoot and the turning of the leaves into coppery green. Soon after, the ants—*Monomorium indicum* Forel attend the nymphs to lick the honeydew and may then be seen hurrying up and down the infested plant. Ten days after the establishment of the nymph the apical leaves begin to curl and fourteen to fifteen days (after establishment of the nymph) the top shoot loses its freshness, becomes coppery-green and curly in appearance. A fortnight after, the whitish leaf-fungus (*Phyllactinea Corylea* (Pers) Karst), which remains dormant, shows itself out prominently on the leaves. Fifteen to seventeen days after the establishment of the nymph the female becomes mature and the males also begin to emerge, impregnate the female and die. The male puparium (as seen in most of the cases) is on a separate leaf away from the females. The male puparium consists of whitish, fibrous threads and is situated near the midribs or veinlets of leaves. It is small, cylindrical, made up of cretaceous white curly threads. Several male puparia may be found congregated together near the midrib of a leaf. The male is bright pink, with light pale legs and antennae, with two cretaceous-white, caudal threads. As is usual with the male coccids, they are fragile little creatures, and move about slowly on the leaf stalks, stems, and shoot of infested plants. On a plant the maturing of eggs, the emergence of nymphs, the maturing of females and the emergence of males goes on intermittently, so that, at times it is difficult to separate the successive broods from each other.

In a case under observation, it was found that the growth of the infested plant was retarded so much that there was a growth of three and a quarter inches within the course of a month, and as soon as this growth had taken place it was infested by the nymphs and females, with the result that another gnarled head was formed immediately above the former one. In this case too, the leaves had become coppery green, curled and crisp and were unfit to be served to the worms.

C. S. MISRA.

PUSA,

The 9th November 1916

MULBERRY SILK

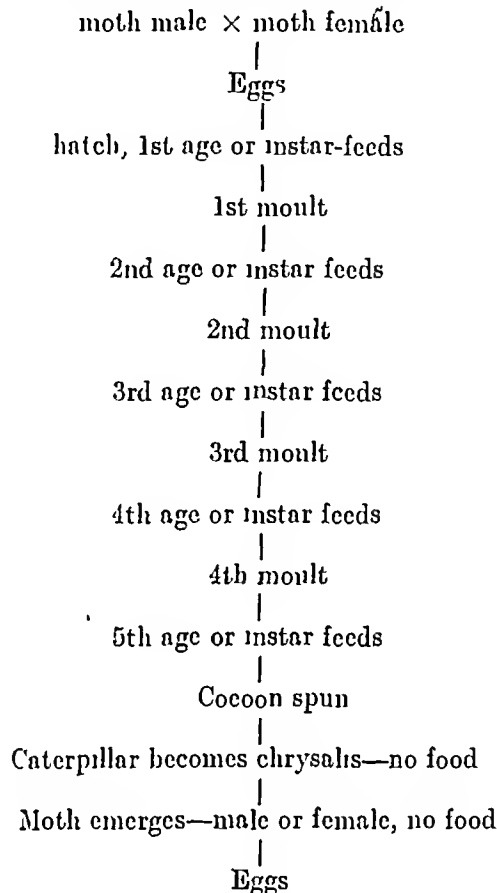

There are certain facts about sericulture which must be familiar in order to follow the subject at all

Silk is the production of a caterpillar, which feeds on mulberry it becomes a moth which lays eggs the cycle is —

Moth male couples with female.

Female lays eggs,

eggs hatch to caterpillars, which pass through five ages or instars, between each of which they moult at the end of the caterpillar (worm) life a cocoon is spun and inside it the caterpillar becomes a chrysalis so you get

All technical terms are margined here for reference

The facts here are abstracted from Maillot and Lambert "Le Traité sur le Ver-à-Soie" where not otherwise stated Japan figures are from Honda "Silk Industry of Japan" They are given for reference and refer to the European univoltine race as a rule

SUMMARY AND CONSTANTS

Eggs are yellow, on being laid, and if they are not going to hatch till they have been through a winter, they turn grey in 5 or 6 days if they are to hatch soon, they do not turn grey The former would normally give one generation a year and are called univoltine = one-brooded the latter in India give several broods a year and are multivoltine or polyvoltine

	gramme	oz.
French, Roussillon, yellow	1,537	38.425
„ Cevennes „	1,431	35.775
Italian, Fossombrone „	1,303	32.575
Cyprus „ „	1,236	30.900
Persia, Sibsevar, white	1,176	29.400
China, Multivoltine „	2,151	53.775
India „ yellow	2,200	55.000

Eggs weigh from 1,200 to 2,200 per gramme

Eggs of univoltine are laid on cloth or paper, kept till winter, scraped off into water and all rejected that float and are then put for hibernation. Changes of temperature are very bad: eggs lose 13 per cent weight in hibernation. Hibernation should be 3 months at 0°C (32° F.) it would rise then 1° C. a day to 22° C. (18° F. to 72° F.) Humidity should be 50 per cent.

In Japan the temperatures recommended are —

December under 40° F, January under 35°,

February under 40° F, March under 45°,

April under 50° F., then 14 days before wanted to hatch raise to 55, then daily 1° to 62°, then 2° to 72° F.

In India, the univoltines should be similarly treated but the multivoltines hatch in 10 days and are kept at normal temperatures.

When the eggs are to hatch, young leaf is put over the eggs if they are fixed, or if loose a fine net is put over and then leaf. Another method is to roll leaves like a cigar, cut it across in pieces and put the spirals down, they are easily lifted off with the worms. The object is to take off the worms. Eggs hatch in the morning, a few the first day, many the second and third, a few the fourth there should be no more.

In Japan, the worms are brushed off the eggs with a feather broom at 11 A.M., 70 per cent should hatch on one day and these are kept, they are mixed up with millet or rice husk, a quart per ounce of eggs, with chopped leaf when the worms crawl up, the whole is shaken up, and perforated paper put over, the young worms then creep up and get on the paper where they are fed.

A few eggs of univoltine breeds will often hatch in 10 or 12 days instead of waiting for the 10 months. These are "accidental bivoltines" and if some of their eggs were to hatch again, they would become multivoltine. If univoltine eggs are wanted to hatch quickly, this can be done to some extent. "brushing" up to the third day makes half hatch. Dipping in concentrated Sulphuric Acid for 30 seconds, then washing, brings out 50 per cent. Strong Hydrochloric Acid, Nitric Acid or Water at 112° F, or hot and cold water (140° F. to 70° F) ultimately does the same, exposure to oxygen brings some out.

Rearing

25 grammes seed	= 36,000 eggs
Weights at hatching	18 grammes
After 1st moult	255 " $\times 15$
" 2nd "	1,598 " " 94
" 3rd "	6,800 " " 400
" 4th "	27,676 " " 1,628
at greatest size	161,500 " " 9,500
at maturity	131,920 " " 7,760
as cocoons	76,250 " " 4,485
chrysalides alone	66,300 " " 3,900
Moths 50 per cent each sex	39,685 " " $\frac{1,700+2,990}{2}$

25 grammes of seed reared by a rearer should give 50 kilos of cocoons, green. It costs in France 100 francs to rear this, and 35 kilos of green cocoons at francs 3 per kilo covers this cost.

Worms are kept on trays space allowed is for one ounce. —

France (old and new figures)

at hatching	3 square metre
after 1st moult	10 " " 5 square metres
" 2nd moult	30 " " 10 " "
" 3rd moult	90 " " 20 " "
" 4th moult	220 " " 40 " "
before spinning	600 " " 45—60 " "

L'Arbousset says that if you allow 40 square metres you will get only 40 kilos, if you allow 60 or 70 you will get 60 to 70 kilos, this is the limit, therefore you provide it

In Japan for one ounce

	first half	at end of instar
1st instar	3—9 square feet	15
2nd „	9—27 „ „	36
3rd „	36—48 „ „	90
4th „	64—90 „ „	180
5th „	180—270 „ „	270

Feeding

	first half	at end of instar
1st instar	7 to 8 times daily	
2nd	6 to 7 „ „	
3rd „	5 to 8 „ „	
4th „	5 to 8 „ „	
5th	4 to 8 „ „	

Table of feeding in kilos (seers) of leaf

	Instar 1	2	3	4	5
Day 1	0 350	1 680	2 800	9 1	16 8
„ 2	0 560	2 800	8 4	14 0	25 2
„ 3	1 120	3 080	9 1	21 0	39 2
„ 4	0 630	0 840	4 9	23 8	50 4

TOTAL LEAF	2 8	8 4	28 0	84 0	512 4
Excrement	05	0 55	1 675	8 675	61 6
Waste leaf	0 65	1 55	7 425	19 325	246 4
TOTAL WASTE	0 7	2 1	9 1	28 0	308 0
Leaf fed			635 6	kilos	= 1,398 lbs
Excrement			72 55	„	= 160 „
Leaf left			275 350	„	= 606 „

Gives 56 kilos of green cocoons = live chrysalides plus cocoons

Leaf should be given fresh, cut square if watery it should be kept till it loses 5 to 10 per cent of water.

30 grammes = 36,000 eggs
 = 30,000 cocoons
 = 60 to 65 kilos of cocoons

L'Arbousset gives feeding as—

Hatching to 1st moult, 4 kilos	=	20	kilos	of ripe leaves
1st moult to 2nd moult, 12 kilos	=	48	„	„ „
2nd „ to 3rd „ 36 „	=	108	„	„ „
3rd „ to 4th „ 108 „	=	316	„	„ „
4th „ to pupation 650 „	=	700	„	„ „

1,192

= leaves for one ounce of Var seed = 60-65 kilos of green cocoons

(L'Arbousset)

Time taken varies

in Japan at 65° F	40 days from egg to spinning
70° F	35 days " " " "
75° F	30 days " " " "
80° F	24 days " " " "

65° F to 75° F is the best temperature for rearing. In Japan trays are

3½ feet × 2½ feet and in rearing nets are used till the fourth stage or perforated paper paper mesh is 0.1 inch, 0.15, 0.2, 0.3, 0.5, to 2 inches

In India nets are used of 0.1, 0.2, 0.3 and 1 inch mesh and cost Rs 45 per 100

Spinning—The caterpillar turns to the chrysalis as a rule three days after starting to spin the cocoon is removed on the sixth and sold on the 8th day

A ripe worm weighs 3.66 grammes,

Cocoon at selling 2.18 grammes,

of which chrysalis is 1.84 grammes,

on emergence moth weighs 1.10 grammes,

pierced cocoon 0.40 grammes

Size depends on the humidity in rearing

	No to kilos	Ripe worm	Cocoon	Silk
Reared in dry air	543	3.51	1.84	0.28
„ normal air	537	3.73	1.86	0.31
„ wet air	500	4.10	2.07	0.34

The humidity should be under 70 per cent at spinning, the temperature should be 75° to 80° if both are higher, the cocoons reel badly

Chrysalis period

at 30° C to 35° C	(86°—95° F)	10—15 days.
at 20° C to 25° C	(68°—77° F)	18—20 „
at 10° C to 15° C	(50°—59° F)	several months
at 2° C	(36°—50° F)	nearly a year

Chrysalides die quickly at 75°—80° C, quicker if air is moist, exposed for any time to 50° C—60° C (112—130° F) they die. Such temperatures are got in India in the sun

Cocoons are picked over and classed as —

Superior,

Medium—deformed, stained, uneven, etc,

Inferior,

Double

L'Arbousset gives these figures —

Fine cocoons	63.7 kilos
Second „	2.1 „
Double „	4.2 „

as the yield of one oz of seed

70

Cocoons weighing 100 kilos at picking at 22° C

weight 1st day	Kilos
„ 2nd „	99.1
„ 3rd „	98.1
„ 4th „	97.5
„ 5th „	97.0
„ 6th „	96.6
„ 7th „	96.0
„ 8th „	95.2
„ 9th „	94.3
„ 10th „	93.4
	92.5

Good French cocoons weigh 500 to the kilo.

For an equal number, female cocoons weigh more and give more silk For an equal weight, male cocoons give more silk

100 kilos fresh cocoons = 84 200 kilos Chrysalides,
0 450 „ moult,
15 350 „ silk,

dries to 32 to 33 kilos dry cocoons,
17 to 18 kilos chrysalis,
gives 8, 9 or 10 kilos raw silk,
8, 7 5 or 7 kilos waste silk

Cocoons are killed with dry hot air at 70° to 80° C for 10 minutes

Moths—Selected cocoons for seed are kept at 70°-75° F Univoltines require 21 days, bivoltines 17 to 18 In Japan paper is put over the cocoons, with perforations big enough to let the moths through, then the coloured excretion of the moth does not fall on the cocoons Moths emerge from 4—8 A M Coupling lasts from one to 5 or 6 hours and is done in the dark One male can fertilise more than one female In “cellular”

Cellular seed production, moths are then isolated to lay temperature should be 75 to 90° F, humidity 70 per cent Moths lay most of their eggs in the next 24 hours

Industrial seed

In “industrial” production, 100 moths lay on one card, only a proportion are examined for disease

In Japan, 100 moths lay 48,000 to 50,000 eggs, of which perhaps 40,000 become cocoons In France 100 “cellules” should contain 35 to 37 grammes of seed = 53,800 of the Roussillon variety

Reeling is done on the Chambon system, two or four threads at a time or on the Tavelette, self-croissure, several threads at a time The former does 18 to 20 grammes per hour of better silk, the latter 25 to 28 grammes of less good silk

Raw silk is judged by its—

Cleanmess (Nettetté) i.e., absence of kinks, knots, etc, estimated by re-winding through a fine point and noting breaks or by examination as it winds with a lens, the best have 50 to 60 “duvets” (ends) per 100 metres, and by regularity, fineness, weight, tenacity, elasticity, brilliance, colour, etc

Conditioning (Titragé)

20 hanks of exact length are run off and weighed, the average is taken and one sees how much each varies from the original The hanks are run off on reel with a perimeter of say 1-25 metre, with a self counter

Hanks are of 400 aunes (476 metres) or of 500 metres, the weight is in grams (0.531 grammes) If 24 times the length is taken the actual weights are deniers but now a silk of 10 deniers is one that weighs 10 grams when 400 aunes (476 metres) are run off Deniers, etc, vary from place to place The last Convention has agreed to take the titre at 450 metres with a weight of 0.05 grammes, a 450 hank of 10 denier silk would thus weigh 0.5 grammes Weight is taken on silk containing 10 per cent moisture (11 per cent added to absolute dry weight)

In a cocoon, the “titre” (size) of the thread varies, the following are figures of successive lengths of 120 metres of one cocoon (Milan) which had lost 4 per cent. of floss —

	Miligrammes
1st length weighed	44
2nd „ „	52
3rd „ „	49
4th „ „	43
5th „ „	37
6th „ „	31
7th „ „	27
8th „ „	23

This varies very much ; one usually gets 100-120 metres of fine silk outside ; then 100-200 metres of thickest silk , then the thread goes steadily down

Tenacity and elasticity—If the thread is pulled it elongates , part of this elongation is elastic, going when the tension is removed, part is permanent (stretching) This is tested by weights and measurements ; the table shows the results on 50 c m. of silk :—

Weight.	Total elongation	Permanent elongation	Elastic elongation
10 grs.	3 M M	0	3 M M.
20 "	5 M M	0	5 M M
30 "	8 M M	0	8 M M
40 "	10 M M	1	9 M M
50 "	13 M M	1	9 M M
60 "	17 M M	1	9 M M
70 "	21 M M	1	9 M M
80 "	26 M M	3	23 M M
90 "	37 M M	9	28 M M
100 "	45 M M	14	31 M M
110 "	57 M M	23	34 M M
120 "	72 M M	33	39 M M
125 "	75 M M	36	39 M M
127 "	77 M M	broke	-

The permanent elongation here noted was observed at once Much of it goes in time and much more if the thread is wetted That is, wetting the thread adds elasticity and so the conditioning is important

The Serimeter is an instrument meant to automatically indicate the elasticity, etc , of the silk

Two or three fibres of raw silk twisted together at 75 to 100 turns to the metre is Tram , (weft)

Two single fibres, each separately given 500 to 600 twists per metrie (12 to 14 per inch) and united with an opposite twist of 400-500 per metrie = Organzine (Warp)

There are other varieties

Twisting is supposed to give strength , it also prevents the subsequent tangling of the thread in working, and also gives different classes of fibre suited to various fabrics Boiling off is done for one hour in a bath of 30 per cent soap and then for one hour in a bath of 15 per cent soap The thread loses 25 per cent in weight

Soie Souple is made by exposing the silk to 90° C in a weakly acid bath

Spun waste is classed (titré) by the number of 1,000 metres required to weigh one kilo No. 150 means 150,000 m = 1 kilo The finest spun is 300 The finest raw silk on this basis would be 1,331, and the single fibre (brin) would be 4,444

GRAINAGE

Seed Selection.

Pasteur's methods

- (1) Never take eggs from a brood showing any flacherie at spinning
- (2) Select moths by cellular laying and microscopic examination

The moths as they couple are isolated in bags of gauze, on squares of cloth, under covers of paper or metal , the male after coupling is allowed to die or pinned in the corner ; the female lays and dies , she is then examined for pebrine The body is pounded in a little water, a drop put under the microscope and looked at with a 1-6 or 1-9 objective.

RACES AND CROSSING

1. *Eggs*—adherent (European and most others),
non-adherent (Turkish, Persia, China, etc).
 - 2 *Larva*—skin smooth, white
 ,, black banded and 2 ventral spots to each.
 Black
 ,, white banded
 Blue (Chinese)
 Green ,,
 with processes—(China),—coloured or white
 - 3 *Cocoons*—White—Oval and spherical
 Cylindrical
 Conical and Cyhndroconical
 Green—Oval (Chinese)
 Cylindrical (Japan and Persia)
 Conical.
 Yellow—Oval (China, Bengal)
 Cylindrical (Europe)
 Conical (Persia, China)
 Cylindro-conical (Cyprus)
 - 4 *Moths*—White
 ,, banded
 Grey or black
- The Mulberry*
Morus nigra
Morus nigra lacinata } Give coarse silk.
Morus alba —Origin in Asia
 Leaf much divided Fruit (white, red or black) is on a long stalk The best for silk
- Morus rubra*
 ,, *celtidifolia* } American
 ,, *insignis* }

Of *Morus alba* there are many varieties, *Morus alba-vulgaris tenuifolia* is a shrub given to young worms because it comes out sooner

Morus alba vulgaris rosea has whole leaves, is used as a graft to form a tree and stands dryness

Morus alba vulgaris Moretti with large leaves, good for hedges, does not stand frost

Morus alba latifolia (*Murcer multicaule*) is good for shrubs and hedges because it grows well from cuttings It has large dentate leaves

L'Arbousset adds *Morus Japonica* a sprout found by M Nourigat at Lunel among a plot of Japanese seedlings It is large-leaved and very early

The best permanent trees come from seed To get seed, get fruits from a tree not too young or old (10 to 30 years), which is not being plucked Collect the ripe fruits and rub them in water till all the seeds fall Collect them, wash and dry in the shade

Sow in loose friable soil, well manured, in lines or beds, the young plants come up in a fortnight, they are replanted after a year (if we sow in July, replant in November or December) a yard apart, the tap root is cut at 8 inches, and the stem above the 3rd eye, when 3 shoots grow two are destroyed and one left to grow Select the best for planting out

Grafting is used for all inferior ones Budding is used for *multicaulis* and *Moretti* Layering is also used for others

The trees are planted out : the tap root is cut, the top is cut, and only three shoots are allowed to grow to make main branches. This is done by cutting the main shoot at the top, letting the side buds grow, and cutting off all shoots from the bottom up except the three best placed to make main branches. The next year these three are cut at say one foot to leave two buds to make branches. In this way an even tree is got

The following gives planting distances.—

	Orchard	Alleys	Border of avenues
Tall plants	5 to 10 metres	10 to 12	10 to 12
Middle plants	2 to 4 „	2 to 4	2 to 4
Dwarf plant	$\frac{1}{2}$ to 2 „	0.9 to 2 m	$\frac{1}{3}$ to 2
Hedges	2 „	1 to 3	
or bushes	1 foot		

If trees show signs of becoming bad they are cut heavily back to be rejuvenated. A single well developed tree gives 200 kilos (seers) of leaf in one plucking. It requires a diameter space of 33 to 35 feet.

APPENDIX XIV.

The note on Wild Silks prepared by Mr J H Watson of Manchester is produced as well as certain extracts about oak feeding silk the remainder consists of reports from forest and district officers on the present condition of the tasar industry, with a report from the Director of Agriculture, Bihar and Orissa

REMARKS ON THE DEVELOPMENT OF SERICULTURE IN INDIA

J HENRY WATSON

The preliminary work to be done would be the complete survey of all the possible wild silks, Indian, Ceylonese and Andaman, and the obtaining of pure wild stock to commence with I am aware that something has from time to time been done but only in sporadic and disconnected attempts but the results obtained are negligible, there being no continuity over a period, which is necessary if the best results are to be obtained This would of course necessitate some travelling with the setting up of a small breeding station in various districts, but, having obtained the pure stock, work in selecting and production of better races could be at once proceeded with As an instance I have had during the last few years collected for me in Assam, *ie*, Dibrugarh, Sib-sagar and Mowphlong, cocoons which are there said to be reared as *Muga* by the natives These cocoons when hatched prove to be those of no less than three distinct species, *Antheraea Assamensis*, *A frithii* and a species which appears to be a form of a *roylei* but which has a cocoon, not double walled as *roylei*, but single walled and hardly distinguishable from *Assamensis* Again in the Bengal and Manbhum districts, it is likely that here, there are *two* races of *Tasar* (*A Mylitta*) masquerading as one species and one race Certain it is that in Assam the race of *Tasar* there is very distinct from the Bengalese and gives different broods One of the things that I should like to do would be to try and separate these two races which I have never been able to do in England with the limited time at my disposal and little material which I have received from India When these two probable races are separated and bred on Mendelian lines you can then in the third generation by selection be sure of obtaining in your cultures the *certainly of results* which has been obtained in the rearing of *Bombyx mori* and which I feel sure is not the case in India with *Tasar* at the present time

The above case is analogous to that of the genus *Cricula* where what has been passing in collections since 1847 as a form of *C trifenestrata*, M André and myself simultaneously by breeding in Europe found there were two very distinct species Cotes in his fine work "Wild Silk insects of India" No 2 plate X falls in the same error and figures the male and larva of *C trifenestrata* but the cocoon and female are *C Andrei*. The segregation as before mentioned in *Tasar* would have to be done in the case of *Eri* silk as the insect I have received for experiment from Pusa is not a pure strain

The species best to use in a *pure state* are the native species as *Tasar*, *Muga*, *Eri* and the *Andamans* species which last I have been investigating for some 5 years, about which so little is yet known, and about which I will speak later

It is of little use to think of the Japanese *Yamamai* as this is *univoltine* with an awkward dormant period as the egg This species is now being superseded by the Japanese themselves by *Antheraea pernyi* which is also an oak feeder and *bivoltine*, with a dormant period in cocoon

state and is more responsive to special treatment in different environments and climates. But there is another species allied to *Perneyi* from Manchuria which is also bivoltine and which I am trying to get alive. This species, also an oak feeder like *Perneyi* (the Shantung silk moth) and the native Indian oak-feeder *A. Roylei*, produces a much paler silk than *Perneyi* and would be the one to rear in the hills on the oaks in India. I have at the moment from various districts in Eastern China and Manchuria 5 distinct classes of Shantung silk cocoons alive and one of these when hatched may be the sought for species which is only known from one in Lyons "Laboratory for Study of Silk" and a cocoon and a short series in British Museum. In any case one of the classes I have, my correspondent who is a Manchester man, now a Shantung silk exporter, informs me he can get 50 per cent more money (as cloth) than the ordinary *Perneyi* cloth.

If this would mate and produce a fertile hybrid like *Perneyi* does with the

Hybrids

Indian *Roylei* it would be the ideal silk producer for the Hills in India and on these lines with other species of close relationship to the Indian species, much valuable research and great advances would be done towards the production of better silks. Wailly, 35 years ago (who was my correspondent some years later) produced under the Aegis of the French Society of Acclimatisation, a fertile hybrid between your Indian *Roylei* and the Chinese *Perneyi* of which I have one female he gave me. It (the hybrid) was accidentally killed after rearing about 5 broods and was never again obtained to my knowledge until 3 years ago I again produced it, both ways being fertile. From the cocoons I obtained, I had a draft of silk made and it is very beautiful, almost pure white like *Roylei*, but the quantity of *Perneyi*. The hybrid was fertile in both crosses and both crosses were bivoltine in Manchester, but 3 broods may be reared in Assam probably, if the hill-oaks were prepared for the purpose. Investigations such as this and the careful selection of the finest strains would lift up the value of both quality and quantity of silk produced and there is no reason why as great a success should not accrue to India by the introduction of such foreign stock, as has been obtained in Sze-chuan and Yunnan in Western China by the introduction there of the East China Shantung Silk moth.

The Andaman Islands (and probably other districts in India and Burma)

D Andaman species.

alone possesses three species or geographical races which I have had sent me the life histories of, together with their live cocoons, and from which I have had drafts of the silk made for me in Macclesfield. These are probably unknown economically in India but I have figured two in my "Wild Silk moths of the world". I refer to *Antheraea Andamana* which produces a very beautiful though dark silk and the other is the large Andaman race of *Actias selene* called *Callandra*. This last produces 50 per cent more silk than the largest Indian *selene* and what is most valuable is that it is a pure white and lustrous. There also is another large *Antheraea* of which I have two cocoons. These are similar to a very large *A. frithi* but the silk is yellow outside but paler inside and I think the colour will be very pale yellow when boiled off.

If I am correct in saying that the Andamans is a convict settlement, it then appears to me that you have here a great opening for silk production with native silk and with labour at a low cost and what is more, placing in the convicts hands some trade which he can take up on his return to private life, but I myself am hampered by the fact that I have not been in India and am unacquainted with the conditions there.

Here the question is rather more difficult as so few entomologists I have

E Other foreign species.

knowledge of have taken the interest and trouble to search out the cocoons and life histories of these wild silks, most have been content to have just the imago in their collections.

There is however nothing that could be used in India from the New World, Europe or Africa but the investigation of Borneo and Indo-Malayan Islands may more than likely produce species which could be used in India and may perhaps be of value in hybridisation, as all are closely related to the Indian forms.

My own latest acquisition is the cocoon of the Assamese *Antheraea Compta* which has a cocoon of fine brown silk similar to *A. Andamanæa*.

There is besides the ordinary silk producers another what might be called a side line. This is the production of silk fishing line from the larva of *Saturnia* (*Eriogyna*) *pyncetorum* of South China and

Haman. This is a business which is very considerable and extremely profitable. It is controlled, so my Japanese agent tells me, by a certain guild in Japan, and which he has often tried to get into. Now in India there is a race of this same species *Saturnia cidosa* (Moore) but it is smaller than the Haman race which I named *Pearsoni*, but if *Liquidambar formosana* and *Cinnamomum Camphora* will grow in India, then the silk fish line production could be there introduced either the pure race *Pearsoni* from Haman or a hybrid race between it and the Indian *S. Cidosa*. The silk of the *Haman* race is also exported (30,000 kilogrammes) and the Silk fish line which goes almost entirely to England is 7 200 kilog. I have living moths at this moment of the South China form from Canton.

To recapitulate. The development of Sericulture in India, etc., would mean the investigation of all sources and species over a continuous period, with travel facilities to the best centres. The examination of the best methods in Europe and China of the carding and spinning of such as could not be direct reeled. The hybridisation and the selection of the finest forms and the elimination of the inferior ones and after the production of these hybrids and races the placing of them on the market in *standard brands* carefully graded as is now done in Japan. If this is done in a proper manner the possibilities of silk production in India with its varied climates is absolutely without limit.

OAK-FEEDING SILKS

There is a very great production in China of silk from semi-domesticated worms grown largely upon dwarf-oaks and this silk, the Shantung or tasar of commerce, is extremely cheap and very largely used as reeled silk and as waste.

So far as can be ascertained the only trials of these made in India are those described in the two notes following, and an extract is added from Sir G. Watt's Dictionary of Economic Products.

Extract from the Annual Forest Administration Report of the School Circle, North Western Provinces and Oudh, for the year 1897-98

(5) EXPERIMENTS.

Para 39 —

At the desire of the Inspector General of Forests an attempt was made during the year to rear the silk worms of the North China Moth *Antheraea Pernyi*. In its native country it feeds on two oaks, *Quercus robur* and *Quercus dentata*, and the problem was to rear it on one of the Himalayan Oaks. The cocoons were received in December 1897 and sent to Chakrata, many of the moths having already emerged in transit. Soon, one by one, they all came out and after pairing, the females began to lay eggs and eventually from these eggs worms hatched out in April and May. They were first tried at Chakrata and fed on leaves of the "ban" oak, *Quercus incana* and "Moru" oak, *Quercus dilatata*, but they did not succeed on this food, so they were tried with the high level oak, *Quercus semicarpifolia*, which fortunately seemed to suit them. As the temperature at Chakrata was too high and the food trees too far away, they were then moved to Deoban, and after undergoing the usual moults 182 of them spun cocoons. Next year, no doubt, in due course, these will produce moths and the life-round will begin again but as we shall know more about their requirements, we shall be able to obtain a better supply of silk.

It is unfortunate that they cannot be kept at a lower level than 8,000 feet, so that it is unlikely that the breeding of silkworms will be taken up by the people of Jaunsar.

Extract from the Annual Forest Administration Report in the School Circle, North-Western Provinces and Oudh, for the year 1898-99

(5) EXPERIMENTS.

Para 40 —

Jaunsar Division — The Divisional Officer reports as follows on the experiment with the *Antheræa Pernyi* silkworm

“ The number of cocoons at the end of the previous seasons' culture was 179 These were kept throughout the autumn and winter months at Deoban, and were brought down to Chakrata in the middle of March 1899 One hundred moths hatched out between the 6th and 17th April, and eggs were laid shortly afterwards These eggs were kept at Chakrata to hasten the process of hatching and as the larvæ hatched out they were put upon leaves of kharshu oak (brought down daily from Deoban) and were then transferred to Deoban themselves 645 larvæ hatched, out of which 390 were still alive and healthy at Deoban on the 1st July, the rest having either died in transit between Chakrata and Deoban or after arrival at the latter place The experiments carried out during the past 2 years clearly show that the insect cannot be successfully cultivated in Jaunsar except at considerable trouble They do not thrive on either morn or bau oak and rearing them in the Kharshu forests is never likely to be taken up to any great extent by the Jaunsaris on account of the distance from their villages of such forests ”

Extract from the Dictionary of the Economic Products of India by G Watt

The author had the opportunity, while on a visit to Manipur, to witness the system followed of rearing the worms and reeling the cocoons The worms were to a large extent allowed to run wild on a scrub of mulberry bushes, and absolutely no care was bestowed on them Yet the silk obtained was of superior quality and the manufactures highly creditable The people were, however, so superstitious on the subject that it was impossible to learn more than the most ordinary facts Judging from the rampant growth of the mulberry bushes and the prevailing climatic features of the State, Manipur, next to Kashmir, would appear to offer the best prospects of a future extension of sericulture in India Labour could be had plentifully, and large expanses of rich land, perfectly level, would be available, which for centuries have not been cultivated, and which bear a wild vegetation that in many respects resembles that of China and Japan The average height of the northern portions of the valley is about 3,000 feet, but much land could be got at even 5,000 feet, in which the humidity and temperature closely resemble that of France or Italy Perhaps no better country exists for the oak-feeding *Antheræa pernyi* than Manipur, so that both “ Chinese tasar ” and mulberry worms might be reared Manipur might, in fact, be described as a land of oaks, and in many respects it possesses the characteristic features of Shantung, the home of *Antheræa pernyi*, which might be characterised as the best of all the so-called wild silkworms

Tasar — The following extracts illustrate the method of rearing and collecting —

Tasar silk — The following is an extract of a report by H H Haines, Esq, Deputy Conservator of Forests, on the Silk Industry in Singbhum

1 *Prices, &c* — The prices obtained for large quantities in this season are as follows —

Muga, Rs 10 per kahan (1,280 cocoons) Perhaps a different species
 Diba, Rs 8 to Rs 9 per kahan
 Laras, Rs 7 to Rs 8 per kahan
 Bogu, Rs 5 to Rs 7 per kahan

A French firm for some time has been engaged in the silk trade, and is believed to buy up half of the 40,000 kahans annually produced in the whole of Singbhum the remainder being purchased by native reelers

2 *Cultivation*—Mr A W Walker who was at one time engaged in the silk trade and has a wide knowledge of the subject kindly furnishes the following information on cultivation

The insects begin to emerge from the seed cocoons with the increase of atmospheric humidity the season thus depends much on the period of the monsoon

The females are placed on thorny branches stuck into the ground in slightly shady places, the thorns are to protect the moths from birds and bats She should pair within 24 hours or is useless for breeding

The period in Coitu may extend for 12 hours to allow all the eggs to be fertilised and during this time the female should not be disturbed She commences to lay soon after separation, the eggs laid during the first twelve hours give stronger and healthier progeny and are kept separate from those laid during the next six hours, after 18 hours the eggs are rejected The selected eggs "Hita" are arranged in a series of leaf pouches made of "Roong" *Bauhinia Vahli* They hatch in 6 to 8 days but must be kept out of the sun, and as soon as this occurs the leaf pouches are hung on the twigs of the food tree.

The food trees are very numerous but the *Terminalia tomentosa* is by far the most generally used for the purpose in Singhbhum, it being pollarded every two years for the purpose For instance, a tree pruned in December 1898, will be used again in 1900, the 1899 leaves prove too rich When the branches of the food tree are completely stripped of foliage, the larvæ are transferred to another, or better still the branches of one tree should meet those of another so that the larvæ can crawl to the next of their own accord The least disturbance affects the growth and condition of the larvæ.

Before transferring larvæ to a food tree the ground beneath the latter is usually burnt to free it from ants and other enemies of the larvæ and the stem is painted round with a ring of juice of the Bhela (*Semecarpus Anacardium*) and small boys are posted under the trees to scare away birds, etc

The larva first moults after 4 days then after 5 days again after 6 days and finally after 7 days, it then feeds for 30 to 32 days and then spins its cocoon

A caterpillar on which a fly or wasp has laid its egg will hasten to spin its cocoon and will often commence from the 20th instead of 30th day Even then it often fails to complete its cocoon so far as spinning out all the silk in its body

3 *Nomenclature origin discussed*—The first lot of cocoons from Daba seed is called Ampatia or Dhulia and is only used for seed The Ampatia is then again used for breeding and the next crop is the Daba (producing the market Daba)

Daba originally came from the forests and as seed is called Langa Laria which after several years rearing produces the marketable silk as well as seed Daba seed never comes originally from the forests as Daba

There is certainly a good deal of confusion in the origin of the four kinds quoted in para 1 and the names Muga-Laria and Bogui are often in Singhbhum only the distinguishing names of qualities of cocoons from a silk producing point of view, e.g., Langa Laria is bought as and reeled with Mugas cocoons, the large Bagues are bought mixed with Dabas, because the cocoons give an equal quantity of silk and of an even thickness and elasticity of thread The people are more particular about inferior Larias getting mixed with superior Bagues

Mr Walker says that the Muga are wild cocoons, but if so there is no difference between Muga (which fetches a high price) and Langa Laria unless the difference lies in the latter being only used for seed He then suggests that Muga is another species, viz., *Antheraea Assama* of which the vernacular name in Assam is Muga This, however, is improbable owing to the complete absence in Singhbhum of the food trees of *Antheraea Assama* which feeds entirely upon laurels and two other trees not existent in Singhbhum

The origin of the names is probably judging by analogy with the custom in other silk producing districts to be found in the season of the crop of which these are about four in the year (often known as cycles) and Muga may be a corruption of what is known in Nagpur as the Magh or January crop Mr Meerza, Deputy Magistrate, who has been engaged in writing a monograph on the silk industry in Singhbhum, quotes the following from *Hunter* Three sorts of cocoons only

are usually known in the district Laria, Bogui, Daba. The two former are obtained from the jungle parent moth and the moths lay their eggs in the growers home in August. The Daba cocoons are reared wholly in captivity. They are ready for sale in September and the silk derived from them commands the highest price."

One or two Kol cultivators whom Mr Meerza questioned say that the Muga is the same as the Daba and comes from the same worm. The peculiarity of it being, that the cocoon is found made between two or three leaves (instead of hanging free from a twig). They said it was very rare.

From H. H. Haines, Esq., F.C.H., F.L.S., Conservator of Forests, Bihar and Orissa

Dated the 1st May 1916

In continuation of my letter No. 657-XXV-P-33, dated the 6th March 1916, and with reference to Mr. Lefroy's letter on the subject of the tasar industry I understand that District Officers have been also addressed on the subject and as they will be in a better position to state statistics of *output*, area under tasar, etc., I shall not attempt to deal with this part of the subject. From the figures of *output* or area under cultivation the 'present position of the industry' would also appear to be in the best manner deducible and I can only state in a very general way regarding districts visited by me that I have seen no cultivation in Puri, Angul and Sambalpur although I found wild cocoons in Sambalpur and this is a large weaving centre and was told that a very small amount of cultivation is carried on. In Palamau the cultivation according to Mr. Hannah is chiefly in the Khurchutta range and I saw practically none in area visited by me. Mr. Draper informs me that the industry is not carried on to any great extent in the Santhal Pargannas. In the Singhbhum district it still seems to me very much alive and Mr. Kirkpatrick has heard that in some years nearly a lakh of rupees worth of silk is purchased in this district. (The Settlement report in fact mentions four to five lakhs as the value in 1898.)

2. Nearly all the tasar cultivation takes place in the *village lands*. The reasons for this are said to be the danger of forest fires killing the worms, and the danger from wild animals to the cultivators themselves as these latter have to be up all night to keep off flying-foxes, owls, etc., from the worms. In consequence of this according to Mr. Kirkpatrick there are very few applicants for permission to cultivate in the protected forests. Mr. Grieve, Divisional Forest Officer, Singhbhum, writes "a good deal however might be done in the protected forests where cultivation of tasar is not at present allowed."

As a matter of fact in Porahat the cultivation in the protected blocks is disallowed under the *Rules*. I am told that were it not so the area under cultivation could be increased. In view of the value of the industry and the fact that the cultivation does not necessitate the entire clearance of an area of tree growth I am of opinion that the Forest Department should allow this cultivation provided that the Asan trees are clean pollarded. This is usually done in Chota Nagpur, though Mr. Draper informs me that the Central Provinces method alluded to in my letter to Mr. Lefroy is sometimes practised in the Santhal Pargannas.

(Extract) — "There was a very little tasar cultivation in the Central Provinces and the industry seemed quite moribund. There the cultivators have a suicidal system of half cutting through the Asan branches and bending them down, instead of clean pollarding as pursued by the Kols and the method was incompatible with the continued existence of the forest."

"In the Palamau division the cultivation is actually carried out in the protected forests and the Divisional Forest Officer states there is practically no control and therefore very little use for expert advice."

3. As regard damage by fire this would only apply to the hot weather crop. In Singhbhum Mr. Kirkpatrick states that the early crop is cultivated in May and June (the resulting cocoons being termed "Larea"). The later crop is culti-

vated in July and August (producing cocoons known as " bogoi ") and he states that the cultivator cannot spare time to go to the forest and collect seed and then to watch the worms in these months. He also appears to think that the game is not sufficiently worth the candle as " the Hos are not generally well enough off to watch for four months over their cocoons as during these months May—August the poorer Hos are generally working at road work, Sabai-cutting, etc., and moreover, they want to collect Mohuwa flowers, etc." He quotes the rates of sale as 200 cocoons per Re 1. Mr Kirkpatrick states that he cannot offer any suggestions for improving the industry.

In Palamau the cultivators appear to confine themselves to a single crop. Mr Hannah says that immediately after the transplantation of paddy in August the cultivators commence the rearing on Asan trees and gather only one crop at the end of October. He states that there are three *qualites* of cocoons Munga, Lunga and Fuka and the market rate is about Rs 3 to Rs 4 on an average per Kahan (1,280 cocoons). Mr Hannah estimates that the raiyat *makes a very good thing* out of the cultivation.

In Singhbhum Mr Kirkpatrick says the rates for sale are 200 cocoons per Re 1 and yet the industry is only for the more well-to-do. I presume that the poor man has to wait too long for his money so that possibly Takavi advances to the poor cultivators might assist matters.

4 On the question of a Sericultural Farm and expert advice it should be mentioned that such a farm was established in Chaibassa a few years ago but failed. Mr Grieve believes this was due to mismanagement but is unable to ascertain for certain what the reason was. I might state that I do not think Chaibassa a good place for the farm. It is very hot and exposed to the violent west winds in May and is therefore not particularly suitable for Asan, or, I imagine for the worms. I believe however there is *great scope* for a farm and expert advice.

The question of good seed has always appeared to me the great difficulty and Mr Grieve again alludes to this. He says " It is said there is great difficulty in obtaining seed cocoons, wild cocoons are used for seed purposes and these are generally obtained from the forest, but owing to the scarcity of the wild cocoon the collection is laborious and expensive."

Mr Kirkpatrick says " out of the resultant cocoons some are kept for seed and the major portion sold " but I am not sure whether the early crop is not always raised from wild seed and at any rate for some reason or other I recollect that great stress was laid on the necessity for wild seed.

Mr Hannah says " the seed is bought from the bazar " This bazar seed doubtlessly is brought in from the forest and is expensive. Why is it so necessary under the present system to obtain wild seed? I presume that a large percentage of cultivated seed is infected and this difficulty with seed alone is well worth the attention and advice of an expert.

In addition to the reasons given by Mr. Kirkpatrick (mentioned above in paragraph 2) for not cultivating in the *protected forests* he gives the interesting item " A species of Ichneumon fly is also a great danger and these are cleverly caught by the Hos with bird-lime on a much forked branch of brush wood "

5 To summarize therefore it appears to me that the position of the industry might be greatly improved with the help of Government—

- (a) by providing cheap and good seed (This alone necessitates an expert)
- (b) by opening out more of the protected forest area to cultivation
- (c) possibly (with expert advice) by offering Takavi loans to the poorer cultivators who cannot wait for the returns of their labour for so long as is necessitated by tasar cultivation
- (d) by general expert advice to cultivators.

The following is a summary of N G Mukerji's classes of cocoons —

(Larya) *Narya* —Small-wild—out in June

Gives *Ampatia* —A flimsy cocoon in July-August

Barsati —October—Main crop.

Jaddur —Cold weather crop

Muda-Muga —Wild cocoons, found in the *Ampatia* but the moths do not emerge in August but next June These produce the *Daba*

Daba —Emerge in June and give an *Ampatia* brood and a *Barsati* brood

Bugur —Emerge first in September and give a *Barsati* crop only in November and December If this is correct.

Larya is 3 brooded

Daba is 2 brooded

Bugur is 1 brooded

One thousand two hundred and eighty cocoons produce $1\frac{1}{2}$ —4 lbs reeled silk *Barasati* cocoons fetch Rs 8-10 a kahan *Ampatias* fetch Rs 2-3

MUKERJI—1907

Extract from G R No 3533 of 6th April 1907, R D on Sericulture

I have the honour to subjoin the remarks of Mr Osmaston, Divisional Forest Officer, on the subject —

“The Tasar cocoons can be had in all the ranges of this Division but in largest quantity in Navapur, Taloda, Nandubar, Pimpalner, Shirpur, Shahada and Akran

“The cocoon is found most often on the Bor (*Zizyphus*—*Jujuba*), next to this they are found most often on Sadada Arati Murmult, henkal, niwar khair, babul and dhavda

“At present the cocoons are not much collected, in Shirpur, for instance, Dhangars (not Bhils) collect them to a small extent and use the silk for making very tough string and small boxes and also for preparing a medicine from the pupa inside the cocoon for giving as a tonic to children

“In Taloda Bhil boys bring a certain number of cocoons to the market and sell them for about 1 pie each

“My estimate of the number of cocoons available annually is as follows —

Shirpur	50,000
Shahada	50,000
Taloda	30,000
Akran	50,000
Nandurbar	50,000
Navapur	50,000
Pimpalner	30,000
Dhulia and Nizampur	10,000

TOTAL 320,000

But this estimate may be very wide of the mark indeed

“Wild tribesmen would willingly collect the cocoons if a fair price were offered them Eight annas per 100 might first be tried and I would undertake to collect them at the head-quarters of each range and forward them to any central depôt that might be fixed on if I were given money for the purpose

“When a demand and trade in the cocoon is once established the collection might be done by contractors to whom the right should be sold annually

“The contractor would have to be bound by a clause in the agreement not to collect cocoons unless the insects had emerged or otherwise the supply would decrease and the moth would eventually be killed out”

2 Perhaps a sum of Rs 500 or Rs 1,000 might be placed at Mr Osmaston's disposal for an experiment

I have, etc ,

(Sd) G S CURTIS,
Collector of Khandesh

The leaves of the *asan*, *asam*, or *sajja* tree (*terminalia tomentosa*) are the favourite diet of the silkworm * The insect has no special name of its own but the industry of collecting the cocoons is generally spoken of as *loa*, which literally means a cocoon, and this term is sometimes loosely applied to the worm itself. The collections, which are chiefly in the hands of Kools, Bhuiyas and Dusadhs, are all made in the wild country south of Ahraura, beginning with the jungles on the Vindhvas and going on to Dindhi and the extreme south. The tract where cocoons are found is divided into circles, each man having the right to collect from his own circle and paying the *zamindar* dues as for other jungle products. Good, large, strong cocoons to the number of 300 or 400 are selected by each collector from the November crop, put in earthen vessels, and brought home. At the beginning of the following rains they are taken out and hung up in a position from which leaves of the *asan* tree are easily accessible. After a short time a moist spot is observed towards the upper end of the cocoon. This indicates that the moth within is preparing to break the shell and emerge into the light of day. The moths are of a beautiful russet colour, their wings are edged with a greenish-grey line in front and a red and white band behind, and on each wing is a spot about the size of a big pea, in the centre of which is a transparent membrane similar to beetles' wings. The length of the body of the moth is a little less than two inches, while the breadth from tip to tip of its wings when fully extended is over six inches. The female moth remains in the empty cocoon while the male flies about. The moths enjoy their winged existence only for a day. In the afternoon the rearers prepare a *chauka* or plot of ground plastered with cowdung, and place the fertilized females on it, where they begin to lay their eggs soon after dark. Two or three of these are tied together to prevent escape, and about 100 or 150 eggs are expected from each. The eggs are collected in an earthen pot. Next morning the heavy eggs are picked out from the light ones, either by means of a winnowing fan, called *sup*, or by throwing them all into cold water, when the light eggs float on the surface. The selected eggs are next tied loosely in pieces of cloth and placed in a *nand* for about a week, the mouth of the *nand* being covered with a piece of cloth tied lightly round it. After eight days the *nand* is opened, and small worms about one-tenth of an inch long are seen to have been hatched out of the eggs. These worms are then placed in a *dauna* or platter of *tendu* leaves, and hung up from an *asan* or *lahor* tree. The *dauna* is a hollow made up of two leaves stitched together and kept stretched by means of small twigs inserted within. The worms make their way out of these artificial shelters and begin to devour the leaves, from these they spread to the branches, and as the latter become denuded, they are cut off with the worms and attached to other trees in full leaf. This process is continued for several weeks, until the worms are matured. September is the time when the tasar worms attain full maturity and begin to spin their cocoons. Each seeks a convenient nest and builds up the cocoon in about three days, the inside being composed of silken fibres and the outside covered with a hard shell which protects the chrysalis till it grows into a moth. The September chrysalis soon emerges as a moth and lays its eggs, from which the worm hatches out, grows to maturity, and builds the cocoon of the second generation by the month of November. It is the November crop which goes to market, a few cocoons being still retained and hung up in the forest for the perpetuation of the species next year. The estimated average output is between 4 000 000 and 5 000 000 cocoons a year: and these are sold to traders of the Patwa caste, who come from Ahraura to purchase them, at a price varying between Rs 4 and Rs 10 per 1,000. The September cocoon, without the insect, weighs about 16 grains, and the November cocoon about 26 grains. From every hundred pounds of cocoons about 14½ lbs. of raw tasar are obtained, having a length of 2 082 500 yards. This sells at about Rs 3-8-0 per pound. There are several superstitions connected with sericulture. During the period when the worms are on the tree the proprietor remains in a state of ceremonial defilement. If he violates the rules laid down, it is believed that the silkworms will die.

* I have been in the hospital since the 15th of June. I have been in the hospital since the 15th of June. I have been in the hospital since the 15th of June.

* Incorporated in S.H. Exhibit. By Yves A. Loe, LSC, 1999, pages 1 and 25 to 28.

From the Collector of Bhagalpur, Bhagalpur

Dated the 24th October 1916

I have the honour to state as follows after having enquiries duly made on the Tasar Industry in this district —

- (1) Tasar weaving is still carried on in this district and has not declined to any appreciable extent
- (2) There appears to have been no shortage in the supply of cocoons in recent years. But the manufacturers who produce coloured pieces and the merchants who deal in them have been working at a disadvantage, of late, due to the very abnormal rise in the price of colouring material (German dye) on account of the present war
- (3) The weaving population in this district are, as a class, poor people and can hardly earn anything beyond their daily wages as they have to depend entirely on the local mahajans who take advantage of the situation by supplying materials at such higher prices and by making larger profits in marketing the products. Any measure calculated to make the weaver less dependent upon these mahajans is likely to place the industry on a more sound basis. The starting of some experimental co-operative societies among the Tasar weaving population here, with this object, is already in contemplation. An increased supply of cocoons with a corresponding cheapness in price will undoubtedly benefit the people engaged in the Tasar Industry
- (4) So far as information is available from the weavers of this district the cessation of the large purchase of cocoons by Messrs Norris Payen & Co has not affected the cocoon rearing industry

From L E B Cobden-Ramsay, Esq, C I E, I C S, Political Agent, Orissa Feudatory States, Sambalpur

Dated the 24th May 1916

The Dhenkanal Darbar has been willing to supply the information you ask for and I accordingly have pleasure in forwarding the same. I observe you only ask for information as regards Dhenkanal whereas the Imperial Silk Specialist also asks for it as regards Mayurbhanj. I accordingly forward a note from the Mayurbhanj State on the subject, I observe that there is no request for information as regards the Sonapur Darbar where the industry is a very important one and the Bhuiyas are largely engaged on this work and some of the finest tasar weaving is supposed to come from Sonapur

(Sd) DEWAN,
for Feudatory Chief

RAJ OFFICE DHENKANAL
The 12th-13th May 1916

Note on the position of tasar industry in the Mayurbhanj State

The number of weavers in this State is approximately 500 families, of these 200 are in Bamanghaty, 40 families in Kaptipada Sub-Division, 2 in Panchpir Sub-Division and 35 families in Perganna Upperbhag in the Sadar and the rest in Pergana Olmera also within Sadar. There are about 425 looms in work.

(1) Tasar weaving in this State is still carried on and has not declined except that during years of scarcity there occurs a temporary set back. The industry was declining but the opening of the Kalimati Gurumahisani Railway has given a great impetus to the tasar weaving industry in the Bamanghaty Sub-Division. At Olmera* and other places in Mayurbhanj except Bamanghaty, the weaving industry is stationary or tending to decline.

* An isolated pargana in the Midnapur district. Bamanghaty weavers now go to Kharagpur, Sakchi and Chakradharpur and other intermediate stations in the Bengal Nagpur Railway and sell their fabrics at good prices. Up-country men in these places purchase pugrees and Bengalees Chaddars. The decline in some places is locally attributed to dearth of cocoons and want of capital. The former grievance has been in a large measure removed by the fall in prices of cocoons. In Upperbhag out of about 35 or 40 families, only 5 or 6 weave tasar fabrics. The Patras are undoubtedly very poor and this year the general scarcity has hit them harder than most because they cannot buy any of the raw materials of their trade. Their head-men say prices have trebled for some classes of silk goods they make and gone up all round but the increased difficulty of obtaining cocoons and the rise in cost of living have more than balance rise in prices.

2 There need be no shortage of cocoons in this State. For more cocoons are reared here than are wanted by home weavers. Hence the major portion of the cocoons is exported. The amount collected is also growing larger. In 1914-15 Rs 7,428-5-7 and in 1915-16 up to 31st January Rs 7,935-9-10 were collected from royalty on tasar cocoons. As all this increase is certainly not due to wider collection of wild cocoons it is evident that tasar rearing also is improving.

3 In this State at present no measures are necessary to restore the industry except that it is necessary to lower the prices of cocoons to enable home fabrics to be put on the market at lower prices. A proposal is now afoot to supply cocoons to weavers free of all duties and to remit any taxes leviable from rearers. The matter is under the consideration of the State Departments concerned. The supply of cocoons would also be increased as more cocoons would be reared on the removal of taxes payable by rearers.

4 I do not think advances of money from the State at least in petty and unsecured doles, is of any use. Rs 1,000 was spent in such loans. Rs 500 is given in this particular village (village Bhinjua in Bamanghaty) and they admit nothing has resulted nor was the loan used for the purpose of trade. They them-

selves suggested Rs 25,000 for the Sub-Division of Bamanghaty. They were however willing that a jointly responsible band of the better off weavers in each village should take a more modest loan, and declared they could find security. I have asked the Padhans to send in the names of such guilds in their own village to the Sub-Divisional Officer and he will have their security checked if we decided to allot further loans for this. Apart from finance the weavers themselves suggested other reasons for decline in the industry and methods of possible State help.

- (1) If they import cocoons from Chaibassa where the best variety (dapha) is found. They pay no royalty, whereas if they collect them in Mayurbhanj they pay a royalty which works out to about an anna per hundred cocoons.
- (2) The whole of their stock, except a few local orders used to be taken over by mahajans who had already advanced the whole price to the weavers to purchase cocoons. Since last year mahajans have refused advances owing to security.
- (3) Cocoons are very scarce and the price has risen enormously owing to wholesale export to Chaibasa, Bilaspur and the west.
- (4) The great grievance is the forest royalty and its accompaniment of petty *abwabs* by forest menials. They declare that if this were removed far more cocoons would be gathered and even reared.

5 I find the forest revenue from cocoons in 1914-15 was Rs 7,528 and for 1915-16 up to January 31st Rs 7,935 which will work out to somewhere in the neighbourhood of Rs 9,000 for the year, i.e., our revenue from this source is rising and is already considerable. As a business proposition I feel sure the protection of this infant industry at the expense of forest revenue would be a blunder.

6 We could do something for the weavers by remitting all royalty on cocoons collected for *bonâfide* home manufacture. One possible way of doing this would be to have a central Depôt at Bahalda to which collectors could bring their cocoons. They would pay the forest royalty at the usual rates and in the usual manner but would get a rebate of this royalty at the Depôt. This Depôt would then sell to the limited and known weavers community in Bamanghaty at a price fixed by the State.

7 If the forest revenue is not considered the course is completely easy. By remitting all collection charges and putting a high export duty on cocoons taken out of the State we should lower the price of raw material by half. This would incidentally ruin the export trade which is a source of rising profit to the State as shown above.

8 Messrs Norris Payen & Co generally purchased cocoons in the Singbhum markets. Their withdrawal from the market has caused a decline in the value of cocoons from 25 to 75 per cent and this proportionately benefited the weavers although at some loss to rearers. The result of their withdrawal from markets is not perceptible in case of rearing of cocoons. The price of cocoons in Bamanghaty rose as high as one *Pan* per rupee 4 or 5 years ago, but now the price is about half of that or even less.

9 The weaving industry does not make marked progress in Mayurbhanj for want of organisation and capital. There are no markets for sale of tasar fabrics. There are no mahajans to advance money or buy fabrics. Several mahajans from Ganjam District come every year to Bamanghaty and advance Rs 6,000 or 7,000 and buy some coarse fabrics suitable to their country. Good weavers are reluctant to accept their advances as their work deteriorates by weaving these coarse cloths. Dyeing is declining for want of dye stuff owing to war. At Olmera there are some local mahajans who owing to the close proximity of railways and the nature of fabrics produced have a ready sale. But as the most of the weavers at Olmera are confirmed opium eaters or madat smokers their condition remains as before, and no improvement is perceptible. Except at Binjhua in Bamanghaty and in Olmera the weavers are also cultivators, and treat tasar weaving as a secondary occupation. Thus many looms are kept closed during the continuance of agricultural operations.

10 I may add on hearsay evidence, that it is probably no use improving the local cocoon. The Patras do not rear the silk worm. This is done by Sonthals.

and Koles and each kind of cocoon has its own peculiar deity to be appeased. Again, all the time the cocoon is being spun, the rearer cannot look on a woman's face and has various ceremonials to perform. When asked if they would take up Dapha cocoon cultivation if given seed free the aboriginals refused, alleging they knew not the Dapha Gods nor their ways.

From the Feudatory Chief of the Sonpur State

Dated, the 19th June 1916

I have the honour to let you know the following informations as desired by you:—

- (1) Tasar weaving is still carried on in this State as a cottage industry and it has declined to an appreciable extent.
- (2) There has been of late a shortage in the supply of cocoons. The local produce is not sufficient and the weavers go as far as Chakradharpur and Chaibassa to get their supplies. Owing to the shortage of supplies and the consequent high price of the cocoons, the price of the tasar has increased. So the people who could in former times wear tasar cloths could now ill afford to do so.
- (3) The people engaged in this industry could no doubt benefit if the supply of cocoons was materially increased. But they should be taught the modern improved methods of weaving and should acquire some elementary knowledge of sericulture, otherwise their products would not be able to find a good market elsewhere. It may however be noted here that the cocoons procured from local forests and from the forests of the neighbouring States produce better silk—better in lustre, than that produced from cocoons of the Chakradharpur district.

From W E Ley, Esq., I C S, Deputy Commissioner, Chanda

Dated, the 17th April 1916

I have the honour to say that in all the localities mentioned in the list received from the Imperial Silk Specialist Tasar Silk Weaving is still carried on by a class of persons known as Koskatis and the number of families engaged has not declined to any marked extent. The supply of cocoons varies considerably from year to year and the price this year is double that of last year. This year the crop was damaged by excessive cold and prices are high.

The price of tasar silk varies little from year to year. Consequently any increase in the price which the weaver has to pay for cocoons falls almost entirely on the weaver. When the price is high, less silk is woven and the weaver resorts to other occupations. The people engaged would undoubtedly be benefited if the supply of cocoons were more constant. A large increase in supply of cocoons is not required as the total number of people engaged in tasar weaving is small.

From the Political Agent, Chhattisgarh Feudatory States, Raipur

Dated, the 17th-18th May 1916

I have the honour to state that the tasar industry is reported to be thriving in the Sarangarh, Raigarh and Sakti States of this Agency. Copies of the reports furnished by the Feudatory Chiefs of Sarangarh, Raigarh and Sakti giving information regarding the industry in their respective States are enclosed.

From the Feudatory Chief, Sarangarh State

Dated, the 21st February 1916

I have the honour to say that tasar weaving is still carried on and has not declined but is flourishing. There is no deficiency in the supply of cocoons.

which are locally produced to some extent, and mostly they are obtained from Chaibassa, in Manbhum District, Bengal. The largest number of varieties and the largest sized cocoons are reared and sold in the Chaibassa Market. There are 53 families engaged in tasar weaving, and the outturn amounts to Rs 5 to 6 thousand a year. They work in tasar weaving for 5 months (November to March) in cold weather which is the most suitable season, and during the rest of the year, they engage themselves in making cotton piece-goods. If the supply of cocoons is increased or if they are supplied with cocoons at their homes, undoubtedly both the weaving works and the yield, will be very large.

From the Feudatory Chief, Sakti State

Dated, the 11th-5th March 1916

For want of large demand from outside, tasar weaving has slightly been affected during the last 3 years. Weavers had to make special arrangements to go to Chakradharpur and Chaibassa for purchasing cocoons, where they get at the rate of Rs 12 to Rs 14 per 1,000. These can also be had from the adjoining States, but in quality they are much inferior and as such are sold at Rs 9 to Rs 10 per 1,000. The latter are not however preferred by the weavers in general. During the rains the supply of cocoons they bring in from places quoted above fall short and only the well-to-do weavers with sufficient stock in hand take the advantage while others in normal condition engage themselves in agriculture.

If instructions based on improved methods together with sufficient supply of cocoons can be had on easy terms and with less inconvenience to the weavers the business is sure to be benefited materially.

There are about 60 families engaged in this industry in my State

From the Feudatory Chief, Raigarh State

Dated, the 26th April 1916

I have the honour to furnish the following informations called for regarding the Tasar Industry —

- (1) The tasar weaving is still carried on in the State and it does not seem to have declined to any marked extent.
- (2) There is some shortage in the supply of cocoons as Gandas, who rear tasar cocoons do not know the proper method of rearing and no other people except them would like to do the work. The produce of cocoons does not meet the want of the people of weaving class whose number has much increased than before, hence they have to import them from Chaibassa in Bengal and neighbouring States at much expense.
- (3) If other people also are engaged in it and they are taught the proper way of rearing tasar cocoons there is much hope that the industry will improve.
- (4) The families engaged in tasar weaving are about 100 in number.

From P M Baker, Esq, I C S, Officiating Deputy Commissioner, Bilaspur

Dated, the 24th June 1916

I have the honour to state that the tasar weaving industry is still carried on in this district, and it is on the increase in the Bilaspur, Janjgir and Katghora Tahsils, while in the Mungeli Tahsil it is not in such a flourishing condition. This is due to the shortage in the supply of cocoons, the high rates at which they are sold, the poverty of the weavers and consequent dependence of the weavers on advances from money-lenders.

2 It is stated that cocoons used to be produced in the Lormi and Ratanpur ranges, but the supply there failed some ten years ago. Formerly, the rates varied from Rs 2 to 3 per thousand cocoons, but now range from Rs 10 to Rs 12 per thousand. The present supply is obtained from Chaibassa near Chakradharpur.

3 An increase in the supply of cocoons would probably lead to a drop in prices and so benefit the industry. And the same effect would be obtained by the formation of a Co-operative Credit Society of weavers in each Tahsil co-operative buying in large quantities would enable the weavers to make better bargains and free them from the high rate of interest at which they borrow from money-lenders at present

From G E R Graham, Esq, I C S, Deputy Commissioner, Bhandara

Dated, the 24th-26th June 1916

1 * * * * *

2. Up till 1904, a number of Koshti families were carrying on tasar spinning business in different parts of this District but it has gradually decreased since then and many of the Koshties have left Bhandara and settled down at Nagbhir in the Chanda District owing to the facility of Railway communication. There are however a few families still residing at places shown in the margin but their trade has practically become nominal as it has proved less paying to the labourers than any other work. The Kosa cloth is more costly than ordinary cloth and has less demand in the market, which also contributes towards decline of the trade

From 1 families

Ekodi and Rampewada 20 families

3 Tasar weaving business is not carried on in this district nor was it carried on before

4 There has been no shortage in the supply of cocoons but the industry has chiefly declined owing to the facts indicated in paragraph 2 *supra*

5 As there are few families of weavers residing in this district, no special measures are needed to revive the industry. The increased supply of cocoons would not benefit them

From the Collector of Burdwan

Dated, the 8th May 1916

I have the honour to say that tasar industry is carried on, on a very small scale in the Sadar and Katwa sub-divisions of this district. I enclose copies of report on the subject from the Sub-Divisional Officer, Sadar and Katwa, for your information

Enclosures

- 1 Report of the Sadar Sub-Divisional Officer, dated the 30th April 1916
- 2 Katwa Sub-Divisional Officer's letter, dated 2nd March 1916

Note

The tasar industry in the Sadar Sub-division is confined to the marginally noted villages and embraces about 500 families. There has been a marked decline since the outbreak of the European War, but the weavers are still clinging to it, because they cannot pick up new tricks and also because the people are prone to be conservative and tradition bound. For a period of about six months the industry was wholly paralyzed but has since October last begun to look up. The causes of the depression are not to my mind very clear. The tasar clothes are ordinarily exported to East Bengal, Assam, Ceylon, and Turkey in Europe. The flood in East Bengal and the temporary depression of the jute market are commonly supposed to have crippled the resources of the purchasers and to have brought about the break down of the tasar industry. I do not think that they wholly account for the sudden and extraordinary decline. The fact remains that the cloths were exported on a fairly large scale to Turkey in Europe. The outbreak of hostilities with this country and the necessary tightening of blockade go far to explain the situation. Further more the general contraction of export trade has affected the industry in some measures

- (1) Memari, (2) Tantigantar, (3) Radhakanta pur, (4) Jagadabad and Panchakut, (5) Mankar (including Jagatpur), (6) Kota

There is no doubt that the price of cocoon has gone up to an appreciable degree owing to local causes. If the supply is materially increased it would to some extent benefit the industry. Unless and until demand for tasar cloths is stimulated it is not possible to improve the situation substantially and this will not happen until the war is over.

B N GUPTA

The 30th April 1916

From Babu Jatindra Mohan Banerji, Sub-divisional Officer, Katwa

Dated, the 2nd March 1916

1. Tasar weaving is still carried on but it has declined to a certain extent
2. The industry has decreased for short supply of cocoons and also for want of fast red colour on account of the European War
3. If cultivation of cocoons can be materially increased and fast red colour sufficiently supplied, the industry can be restored to its former position and the people engaged in it would be benefited

There is no tasar industry in Katwa town but it is carried on in some villages in the sub-division, viz, Baghtikra, Singi, Chanduli Masthul, Ghoranash, Gopekhanji, Sribati and Madhabpur. Cocoons are imported from Chaibassa and Baharagara in Singhbhum, Pachamba and Giridi in Hazaribagh and Gobindapur in Manbhum. Cocoons are generally reared in those districts by Sonthals but many of them are now engaged in coal mines on better pay and most of the jungles have been turned into arable fields. These account for the short supply of cocoons.

From G S Dutt, Esq, I C S, Collector of Birbhum

Dated, the 10th April 1916

I have the honour to state that tasar weaving is still carried on in the five villages named in the letter under reference but has greatly declined. The total number of families employed in this business is about one-tenth of what it was up to the year 1904, the majority of weavers having taken to cotton weaving. The reasons of this decline are the rise in the price of cocoons due to insufficient supply and the falling off in demand owing to competition with foreign goods especially with Japanese silk. It is difficult for the tasar weavers to obtain supply of cocoons from Singhbhum as the expenses incurred are prohibitive. If means could be found to supply cocoons at a cheaper rate, the weavers will be in a better position to compete with foreign goods and there is every chance of the industry reviving.

BANKURA

Tasar weaving

In the Sadar Sub-Division tasar weaving is still carried on at Gopinathpur in Bankura Town, Rajgram, and Rajhat Birsinghpur. It does not appear that the number of families engaged in the industry has decreased, but the industry has somewhat declined and this is due to circumstances explained below.

2. There has not been any shortage in cocoon but prices have gone up enormously both in living and in price of cocoon. The price of yarn 15 years ago was 11 to 13 tola per rupee but now it is 7 to 8 tola per rupees. The cost in living has gone up 75 per cent. To a person who formerly required a capital of Rs 50 for a loom it now requires Rs 150. The weavers have thus to reduce their wages in order that the price of cloth did not go up very much. Formerly the wage earned by a weaver for making a 10 cubit cloth was Rs 1-12-0 but now it is Re 1-8-0. Still the price of cloth has gone up. Formerly a *Kete* (10 cubits length) (*Kete* is a coarse variety) cost from Rs 2-12-0 to Rs 3-4-0 but now it costs Rs 3-4-0 to Rs 3-8-0. Similarly a tasar cloth (10 cubits) which used to sell for Rs 4-8-0 to

Rs 5 now sells for Rs 5 to Rs 5-8-0. The demand for this cloth is also declining. Leaving aside the present year when the demand has gone down very much due to floods in Eastern Bengal which take a greater number of these cloths, the demand is falling on account of competition of cheaper stuff both Indian and Foreign.

3 It would thus appear that a greater supply of cocoon only will not solve the question. Of course a greater supply of cocoon will naturally reduce the price of yarn but unless it is very low and the price of food grains also comes down, the sale of tasar cloth would not stand competition with cheaper stuff, or stuff of same price having greater durability such as *Endi*.

Submitted to the Collector.

HEM KUMAR MULLICK,
Sadar S D O

The 19th February 1916

MIDNAPUR

Regarding letter from the Imperial Silk Specialist about tasar silk industry in this district

I visited the two places Kesari and Anandapur mentioned in the letter and collected the following informations which I set forth in the form of answer to the questions raised in the letter.

1 In both the places, the industry has declined to a very appreciable degree, but weaving is still carried on in both the places. The decline has been more marked in Kesari than at Anandapur. It is said that about 25 years ago, when the industry was at its best there were some 250 families at Kesari working some 400 to 500 looms. Ten years ago the number of looms dwindled to about 100 and now there are about 30 families working about 50 looms.

The decline of the industry at Anandapur is not so marked. There were about 400 families in the palmy days of industry about 30 years ago. They number about 100 now working about 150 to 200 looms. The rapid decay of the industry at Kesari is ascribed to the fact that the Kesari weavers as a rule use more thread in the woof of the fabric and that the finest of their products is not as good as that of Anandapur.

2 The supply of cocoons in both the places is less than that in former years but there has never been any shortage in supply, nor is that taken to be the reason of the decline of the industry. Rather the demand of cocoons being less owing to the decline of the industry in the locality, they are transported to other places. The cocoons are sold in the local market in both the places, but the principal places of rearing are Nayabari, Mayurabhanja, Ghatsila and other jungle Mahals as far as Chaibassa. Between the rearer of the cocoons and the weaver the cocoons generally change hands two or even three times. The weavers seem to have no clear knowledge of the reason for the decline of the industry. They only know that their products are not sought after at the prices fixed by them. Formerly Mahajans used to give advances in money for the produces but now things have been reversed. The Mahajans after disposing of the goods, pay a price to the weavers. The reason seems to be that the hand-loom made fabrics can not successfully compete with the mill-made foreign articles or articles of other places. The Mahajans are not confident that the fabrics will get a ready market at the prices fixed by the weavers.

One more thing deserves mention here. The circumstances of the weavers is bad everywhere and they are not in a position to buy and stock cocoons when they are selling cheapest and to stock their products and sell them when the market is highest.

3 The weaver wants that their products should find a ready market as soon as taken out of the loom, and at the price fixed by them which can never be, material increase in the supply of cocoons may help them to some extent if it tends to lower their price.

It is said that adulterated tasar is used in other places but here both the warp and woof are of pure tasar this is the cause of the enhanced price charged by them.

Finish of the products should be more carefully attended to The weavers neglect this and their products are not so attractive to the purchasers

K C BANERJEA,
Kanungoe

The 2nd March 1916

From the Sub-Divisional Officer, Arambagh

Dated, the 26th February 1916

(1) Tasar weaving is still carried on in villages Brojomohanpur in Gohat P S and Shambazar, Badanganj, Kayapat and Kristogunj in Badanganj P S The industry is reported to have declined to some extent since 1904

(2) There has been shortage in the supply of cocoons now a days on account of which and for want of dyes the price of which is reported to have increased 20 times the industry has decreased to a considerable extent

(3) There are reasons to believe that if the supply of cocoons and dyes, be sufficient, the industry may be improved and the people engaged in it may be materially benefited

From C B Smales, Esq., Conservator of Forests, Southern Circle,

Dated, the 17th July 1916

I have the honour to say that records go to show that the subject of the encouragement of sericulture in these Provinces was taken up by this and the Agricultural Department between 1901 and 1905, but the net result has been failure

Forest Officers loyally endeavoured throughout to bolster up this decaying industry but it must be said that they are not enthusiastic on the subject as the most approved method of providing the necessary feeding for the worms is to cut half through vigorous saj trees and bend them over to get accessible pollard shoots hardly to the silvicultural advantage of the forest Moreover it is accepted that the Central Provinces cocoon is of poor quality even in Bilaspur and deteriorates rapidly southwards

One great cause of the decline of the industry seems to have been the very precarious nature of the crop owing to the prevalence of disease and unsuitable climate These could doubtless be got over by improved methods and better seed, but a worse handicap seems to be, as reported by Raipur, the apathy of the Dhums and the fact that more remunerative lines of employment are open to them I attach a copy of the letter from the Divisional Forest Officer, Bhandara, on the subject

No cultivation of tasar silk is carried on now in Reserved Forests In South Chanda 438 22 acres of B I class forests are leased at 4 annas per acre, and the income of the Dhums cultivating this is estimated to be from Rs 4 to Rs 8 per acre

In Bilaspur, where the best Central Provinces silk is grown, it is only done in Malguzari and Zamindari Forests, whilst in South Raipur there is an export trade from Dhamtan of wild cocoons collected in Government forests, though the bulk are believed to be brought from the Bastar and Kankar States

The matter would seem to be of little interest to the Forest Department Trees on which the silk is grown must be carefully watched for the three months of growth and this is best done in the neighbourhood of villages The trees used must be specially treated and I think that the Agricultural Department is more directly concerned

From Mr M Narainga Rao, Divisional Forest Officer, Bhandara Division

Dated, the 27th April 1916

1. * * * * *

2 In the year 1902-03 the subject of tasar cultivation received a good deal of attention in this as well as in several other districts of the Central Provinces. The Director of Agriculture took up the matter and the Local Administration interested themselves in it. It was even proposed to disforest certain forest areas and place them entirely under the management of the Revenue Authorities for the purposes of tasar cultivation. However, about 1,000 acres of forest land containing *Saj-Terminalia tomentosa* trees were selected in the Wenganga and Patalgarh Ranges and placed under the management of the Deputy Commissioner though this area was not disforested.

3 In his note on the decline of the tasar silk industry in the Central Provinces Mr N G Mukerji said in 1904 that "in spite of these disadvantages, however the spinners and weavers of Chanda and Bhandara make no complaints about lack of cocoons. He further adds that "though the conditions under which the tasar rearing industry is carried on in the southern districts are more unsuitable, there has been no deterioration of the industry as in Sambalpur and Bilaspur. While matters stood thus in the Bhandara district in the year 1904 all of a sudden we hear of a sudden fall in the area under tasar cultivation in the year 1907. Since then the industry is on the decline. From the old records in my office I understand that the reasons for this decline are the decrease that prevails owing to severe cold in the month of November when the chief crop of tasar is collected in this district, want of a good supply of healthy seed cocoons and the poor profits which the industry yields to the Dhimals who are the cultivators of tasar. Another reason which has contributed to the decline of the industry seems to be that the Dhimals get sufficient work in the rainy season from the purchasers of our coupes on cutting poles and firewood and I think they consider that the cutting of wood pays them better than the uncertain profits of tasar industry.

4 For the last three years there has been no tasar cultivation in plots set aside for the purpose in the Government forests in this District. I know here and there some small plots are cultivated in the Malguzari forests.

5 None has yet been able to definitely find out the cause for the decline of the industry though the reasons set forth above are believed to be the cause. It is therefore desirable that an enquiry be made by an expert on the subject. With regard to the position of the Forest Department in relation to this industry it is to be stated that the present method of cultivating the tasar silk, viz., that of first cutting good saj trees at a height of 5' from the ground and then growing the cocoons on the leafy pollard shoots of the trees is against all rational silvicultural treatment besides being financially injurious. If after an enquiry by a silk expert it is found that the cultivation of silk is more profitable both to the cultivators and the Forest Department than by growing saj trees, there should be no objection to the industry being renewed in this district. There is plenty of almost pure saj forests in this district and if good seeds are introduced, and a rational method of cultivation without having to cut down trees at a considerable height from the ground taught to the Dhimals, there is no reason why the Forest Department should not encourage the industry.

Extract from the reports on the Forest Administration of the Central Provinces for the years 1901-02 to 1908-09

1901-02

45 *Bhandara Division*—An experiment in connection with tasar silk cultivation was carried out by assigning areas aggregating 80 acres to Dhimals free of charge with a view to revive the industry. The second crop is reported to have been successful in one place only called Mohghatta, and the third crop in two other places Tambekhani, and Kanhargaon. The Dhimals earned enough from the operations for their livelihood for four months, but they are loth to tell the results. The number of families engaged was 19.

* * * * *

50 Tasar cultivation showed an improvement Forest and Revenue Officials did their utmost to give effect to Government orders recently issued regarding the revival of *kosa bari*. Dhimals, however, were reluctant to take up land permanently on a four-year rotation, and preferred sticking to their usual old haphazard methods of taking up cultivation of an annual "bari" here and there.

They divided their time between tasar cultivation and their other avocations of fishing, etc., and then attributed their losses or small profits to supernatural causes, such as the evil-eye of an enemy, or the wrath of the local deity. The area taken up for tasar cultivation during the year was 241 acres as against 8 acres in the previous year.

1902-03

24 *Bhandara*—The experiment in tasar silk cultivation noticed last year has, unfortunately, been a failure owing to the damage done by four days of frost from the 25th to 28th December, which quite discouraged the Dhimals employed. The area set aside has now been made over to the Deputy Commissioner, and, it is hoped, that with the aid of small money advances, the industry may be fostered.

1903-04

43 In Bhandara, Bilaspur, North Chanda, and South Chanda the tasar experiments were continued with poor success. The Agricultural Department is in a better position than the Forest Department to give the necessary attention to this most important question, and to attempt the revival of the decaying industry with fair prospects of success. To ensure this, arrangements are now being considered whose object is to place suitable portions of the least valuable forests at the disposal of the Agricultural Department for experimental purposes on a considerable scale.

1904-05

48 The cultivation of tasar was continued in North Chanda and Bhandara. In the former 701 acres yielded 163 cocoons per acre, which is very little, but the disease locally called *hugri* destroyed many of the insects. In Bhandara the area increased from 615 to 1,225 acres. The Divisional Forest Officer reports that 39 families of Dhimals took up the cultivation of these silk worms, but the results are not available. The Director of Agriculture, however, has informed me that Mr. Mukerji's proposals involve the ultimate abandonment of the rearing of tasar in Government forests and the consequent pollarding of trees therein.

1905-06

46 *Tasar silk*—The cultivation of tasar appears to be decreasing steadily in North Chanda, where the area applied for this year was only 506 acres as against 701 acres in 1904-05 and 1,760 acres in 1903-04. In Bhandara, however, there was no falling off in the area cultivated, which remained the same as last year, 1,225 acres.

1906-07

47 *Tasar silk*—In north Chanda the area over which tasar was cultivated rose from 506 acres to 811 acres, but in Bhandara there was a sudden decrease from 1,225 acres to 145 acres, for which no explanation is forthcoming.

1907-08

47 *Tasar silk*.—480 acres were set aside for this in Bhandara, but very little actual cultivation was undertaken. In North Chanda 680 acres (against 811 acres last year) were applied for.

1908-09

35. *Tasar silk*—Tasar silk was cultivated over 330 acres in the Bhandara and 308 acres in the North Chanda Divisions. In both Divisions the Dhimals, the only people who do this work, are taking to cultivation which they find more remunerative.

THE TASAR INDUSTRY IN BIHAR AND ORISSA.

Note by Mr H M Lefroy, Imperial Silk Specialist, suggesting an enquiry into the Tasar-rearing Industry in Bihar and Orissa

The last enquiry into the *tasar* industry was made by Mr N G Mukharji in 1904. His report advocated certain measures, the chief being the establishment of seed-producing farms. The farm established in Chaibassa failed and was closed. I pointed out in 1908 that it must fail and the reason, which was that Mukharji entirely missed the point that *tasar* is not one species of insect but several, that until each was got pure, the farms were simply blindly hybridising and producing bad stock, and failure was therefore inevitable. Since then nothing seems to have been done and we have now to decide what to do.

The *tasar* industry used to affect directly probably at least 100,000 rearers and cocoon collectors, with whom it was a subsidiary occupation, 20,000 twistors, with whom it was a main occupation, and 50,000 weavers, who also wove cotton. Of these perhaps 120,000 are in the area included in Bihar and Orissa. So far as the weavers go, we are making direct enquiry into their position as they live compactly in villages and district officials can reach them. So also for twistors. But we cannot do this for rearers and collectors. It is important to inquire in the Chota Nagpur Division and Sonthal Pergannahs—

- (1) whether there is any shortage of supply of cocoons,
- (2) whether this is due to low prices,
- (3) whether there is any distress or poverty consequent on these,
- (4) whether improved cocoon production would be beneficial or is not needed

This can only be done on the spot, needs no technical knowledge and should be done from now to October. The position with regard to *tasar* is this: the industry can be improved by two methods: one is to organise and improve the sale (and production) of cloth, to get wider markets, larger demand: that is easy and cheap; the other is to undertake the scientific enquiry required to put the breeding on a proper footing, which will make the rearing of *tasar* cocoons safe, easy and profitable. This enquiry will be hard, long and expensive, but till it is done, nothing further can be attempted to benefit the rearer and the problem lies at the root of the whole industry.

The question is whether the state of the industry, as regards the rearer, justifies the latter. Has the rearer given up because he prefers to or because he must? Is the decrease in production due to the increase in value of rice and the increase in wages, leading rearers to abandon the less profitable *tasar*, or to inability to get good stock to rear from or to get good results from rearing? Finally, is the decrease due to the Forest Department restricting areas in which rearing can be done?

If it is necessary to revive *tasar* we know what to do. What we do not know is whether it is necessary and this can be ascertained only by enquiry from the class of people who rear *tasar*. Bihar and Orissa are very much interested, the Central Provinces and Bengal very little and then chiefly the *tasar* users.

If the Bihar and Orissa Government can have the enquiry made, it will be possible to advise quite definitely about *tasar*. If anything like 100,000 people are affected and there is real distress, then the scientific enquiry necessary had better be considered and its cost worked out, if not, then *tasar* may be finally left to either continue, decay or revive as circumstances dictate.

H. M. LEFROY

The 6th July 1916

*Report on the Tasar-rearing Industry in Bihar and Orissa by Mr J R Dain,
I C S, Officiating Director of Agriculture*

TASAR REARING

[To avoid burdening the note with explanations of the vernacular terms used, a glossary of the more common words is given in Appendix A. The terms, however, are not always used consistently by the rearers and dealers.]

1 This enquiry into the economic aspects of the *tasar*-rearing industry was undertaken during the months of August and September of this year. For the purpose the following places were visited—Chaibassa, Barkundia, Pandabir and other villages in the district of Singhbhum, Sambalpur, Purulia and Raghunathpur in the district of Manbhum, Giridih, Gande, Mohanpur and other villages in the district of Hazaribagh, Bhagalpur, Tinpahar, Rajmahal, Pakaur, Hiranpur, Dumka and Katikund in the Sonthal Pergannahs. I have also been able to make use of information collected by district and local officers who have all rendered me great assistance. Owing to the claims of other work the time actually spent on the enquiry was strictly limited and could have been extended with advantage, but the places visited are fairly typical, and the conclusions reached, which are corroborated in the main by other enquiries, may be taken as generally applicable. Many points could have been more advantageously studied later in the year when the rearer is putting his *tasar* on the market. The *barsati* crop does not come on the market till the end of October in any quantity, and the winter crop which, though less valuable, is the larger in amount, is sold in December and January. On the subject of prices, it was necessary to depend largely on the information supplied by rearers and dealers, and there is reason to believe that a good deal of it was deliberately misleading.

2 A note by Mr Maxwell Lefroy on which this enquiry is based is attached with this. He propounds in the body of that note four main questions, but the subsidiary questions which are put later in the same note indicate more clearly the scope of the enquiry. The main question is this: is it necessary or advisable to revive the declining *tasar* industry in the interests of the rearer and collector of cocoons? The interests of the twister and weaver are not in question. To answer this question I have endeavoured the almost impossible task of making an estimate of the number of persons who rear *tasar*, and further have enquired into the economic conditions under which the *tasar* rearer works. The following report contains a note of the facts ascertained in each locality visited and answers based on the information so obtained to the seven questions propounded by Mr Maxwell Lefroy.

SINGHBHUM

3 *The trade*—There are several marts in Singhbhum of which Chaibassa is the most important. The chief sources of supply, besides the interior of the district, are Chakardharpur (these appear to be partly imported Hazaribagh cocoons) and the Feudatory States of Mayurbhanj and Keonjhar. The chief centres for export are Bankura, Burdwan, Bhagalpur, Gaya, Bilaspur and Nagpur. The demand though somewhat irregular is on the whole in excess of the supply and the *mahajans* cannot meet it. At present three quarters of the demand is from the Central Provinces and one quarter from all the other places taken together. Taking all the crops the total export is 20,000 to 25,000 *kahans** per annum.

*One *kahan* is equal to 1,280 cocoons generally.

The demand is on the increase, especially from the west. No doubt consumption would rise with increased supplies because there are many weavers who weave cotton as a rule but prefer *tasar* if they can get it. Formerly there were several European firms in the market. Messrs Payen et Cie of Lyons are said to have been trading before the mutiny when they were established in Berhampur. There was according to my information early competition between Messrs Payen et Cie and Messrs Jardine, Skinner and the latter were beaten out of the market about 1889. Messrs Anderson, Wright & Co were here for a time and Messrs Lyall, Marshall worked almost up to the last. The last of all, however, were Messrs

Payen et Cie. The *mahajans* declare that they were beaten out of the market by the Central Provinces dealers. But it appears that it was rather the slump in the Home markets and the competition of China and Japan that caused them to abandon the business. The statement of the *mahajans*, however, does indicate that the Central Provinces market was growing and that when the European firms ceased to buy, the Central Provinces market very rapidly stepped into its place, and this, coupled with the already diminishing supply, prevented any serious fall in prices. The easy railway communication with Central Provinces and the west encouraged the industry a good deal and the demand is said to extend now right up to Bombay. As far as my information goes, there never was a large export of *tasar* from India, most of it has always been consumed within the country. The annual value of the trade to the district is from two to two-and-a-half lakhs of rupees as against five lakhs estimated at the time of the Settlement Report. According to the statement of a "Thiceadar" this is distributed among the marts as follows — Chaibassa Rs 1,20,000, Gambaria Rs 36,000, Chiru Rs 36,000, Jaintgarh Rs 10,000, Tantnagar Rs 36,000, Sarda Rs 18,000, Khotghar Rs 6,000. His total exceeds what I have estimated as the value of the output of the district but it indicates the ratio of distribution between the marts. Of course only a portion of this reaches the rearers of Singhbhum and the Feudatory States and a good deal is stopped by the middleman (*vide* under prices paid to rearers).

4 *Number of persons engaged in tasar rearing in Singhbhum* — No particular persons are engaged in the industry. A man may take it up in any year and drop it again. The rearers are mostly Hos. It is very difficult to make even an approximate estimate of the number of persons engaged in it in any year. The census of 1911 contains no reference to it, presumably because it is not a permanent occupation. Mukharji in 1904 estimated that 500,000 persons were rearing *tasar* in the Lower Provinces of Bengal. He based his calculation on the amount of *tasar* consumed and the average output of each rearer. In the note of Mr. Maxwell Lefroy the figure is given as 100,000, but the facts on which it is based are not indicated. I think that even the latter figure is probably an over-estimate and that in spite of the fact that there is reason to believe that the scale on which *tasar* is reared (assuming that Mukharji's figure of 3,000 cocoons a rearer is correct) has declined to a greater extent than the number of persons doing it. The usual amount produced by a rearer appears to be one to one-and-a-half *kahans*.

The only reliable source of information is the *dalkati* figures and these only for the Kolhan. A statement of these is appended with a note explaining it (Appendix B). The *dalkati* is a tax imposed in the Kolhan on those who "take *ara*" i.e., cultivate *tasar* at Re 1 a head. The figures are explained in a note with the statement where reasons are given for supposing that the number of rearers in the Kolhan is about 8,000. In Dhalbhum pargana the Manager of the Midnapur Zamindari Company informs me that there are 1,029 rearers this year. The remainder of the district is unimportant and perhaps another 1,000 may be added for it, making 10,000 for the district, the chief centre of *tasar* rearing in India [*vide* also paragraphs 14 and 17 (c)].

5 *Rearing and the prices obtained by the rearers* — There are three main crops. In the case of the *daba* crop moths eclose in May and June, pairing takes place at once and when the eggs hatch the young caterpillars are put on *asan* trees and go through four changes of skin and in August form *ampatia* cocoons. The moths again eclose and the process is repeated and in November the cocoons of the *barsati* crop are formed. If the moth does not eclose in May or June but in October, there is only one cycle and the *bugur* crop comes about February. The *larya* appears to be a different kind of moth. It ecloses in July, goes through one life cycle and cocoons for the market are obtained about November. The dealers form a little ring and do not compete to any great extent, but they have not in Singhbhum succeeded in intercepting the increased profits on their way to the rearer in the same way as they have in other places. Sometimes they deal direct with the rearer and sometimes

another middleman intervenes in the shape of a *Tanti* who buys from the rearers and resells to the *mahajans* at a small profit. It must be remembered that the produce as put on the market is not uniform in character throughout, and this makes it difficult to ascertain rates; but the following are given by the dealers as the prices paid to rearers on the average —

	Rs
Larya crop	7 to 8 per kahan
Karik (daba) crop	8 to 9 „
Bugui crop	6 to 7 „

As a matter of fact these are somewhat below the prices stated by the rearers. It was too early in the season to study this aspect of the question at first hand and possibly the *mahajans* have private reasons of their own for giving these low figures. A statement furnished to me by the courtesy of the Bengal-Nagpur Railway Company will show that the cold weather months are the busy time in the trade. A certain weaver of Bankura who acted as a middleman states that the price last year was 100—108 cocoons to the rupee and that sometimes the price goes to 80 cocoons, but that eight or ten years ago the price was anything from 150 to 200. The rearers always reckon by *pans** to the rupee and therefore it is convenient to reduce the average of the *mahajans'* figures to this denomination for comparison —

*30 cocoons and *jandas* (4 cocoons)

Larya crop	2 pans 2 gandas
Daba crop	1 pan 18 „
Bugui crop	2 pans 8 „
Tanti's figure	1 pan 7 „

A group of villages round Barkandia was visited where the practice of using fresh wild seed had been abandoned and the seed was kept from year to year. In Barkandia about 15 people were cultivating *tasar* out of about 148 families. Some of the cocoons now obtained will be distributed and more will go in for the main cultivation. It is said that more are doing it this year than in the last few years. A man who appeared to be a fairly typical case was taken. He had 10 *gandas* of seed cocoons. Out of these he hoped to get 2-3 *pans* of the second seed crop and from these again a *kahan* or so of *adbas* for sale. He will keep 10 *gandas* for seed next year and sell the rest. Last year people who sold early sold at 2 *pans* to the rupee, but those who waited for the market sold at 1 *pan* 10 *gandas*. This is said to be about the usual rate and is slightly more favourable to the rearer than the prices stated by the *mahajans*. About three years ago it went up to one *pan* per rupee, and the large number of reares shown in the *dalkuti* statement for 1913-14 is possibly the result of a temporary impetus given to the industry by these high prices. Similar enquiries were made in a village Khariataga and elicited the information that last year the crop sold at 1 *pan* 5 *gandas* to 1 *pan* 14 *gandas* per rupee, while three years ago it went up to 1 *pan* 2 *gandas*. The average output of a rearer is between one and two *kahans* and his earnings after some months of discomfort and toil in this precarious business are under the best circumstances well within Rs 15. Another group of villages round Pandabir was visited where the wild seed is still used. It is brought from the surrounding Feudatory States and sometimes from great distances. Cultivation was reduced this year as rearers were short of money to buy seed for which they pay a rupee for 5 to 7 *gandas* as well as the export duty (annas 4 a *kahan* from Keonjhar and annas 8 from Mayurbhanj). The cultivation thus costs them rather more than where the domesticated seed is used, but on the other hand they mention a rather better range of prices (15 *gandas* to 2 *pans* per rupee for *daba*). This very slight difference in price is the only evidence which I have been able to find of the supposed deterioration of the cocoon which is denied by both dealers and weavers. Indeed the weakness of the domesticated cocoon appears to be its liability to disease rather than its inferiority as a silk-producer.

It may be noted here that the rearer is not affected in my opinion either by the *dalkat* tax or the export duties, both of which are paid by the consumer. It is the *mahajans* who cry out against them. The *mankis* consider that they have certain rights in the *asan* trees and would put obstacles in the way of rearers who used them without permission. The *dalkat* tax is a fixed rate instead of an arbitrary imposition and the *manki* receives annas 4 of it.

The prices now received by rearers are better than they were formerly, though in the last 30 years they have not perhaps risen in the same ratio as the price of staple food crops. But in respect of the relation between rearer and middleman the conditions in Singhbhum are different to those found elsewhere. The chief cause of decline, however, and of failure of supply to meet the demand must be sought elsewhere than in the prices at which the produce is selling.

6 *Reasons for the decline of tasar rearing in the Kolhan*—The industry has never been more than a subsidiary occupation by which a man might add to his income, but by which he could never earn a livelihood. It is precarious in the extreme. A long drought causes the destruction of the crop and so does sudden and heavy rain. The worm is liable to attack by birds, flying foxes, insect pests and disease. The rearing involves many most irksome and exacting religious observances and austerities which are of too intimate a character for detailed description. These are in themselves a recognition of the large element of chance in the venture. The work is also very laborious and means constant and unremitting watching of the trees to scare away the enemies of the *tasar*. The statement that has been made to the effect that it is light and easy work which can be left to the weaker members of the family appears to be a mistake. A man who is comfortably off will not take the trouble to rear *tasar*, on the other hand, a poor man can hardly afford to spend two or three months on work that is not bringing in money all the time. If he has cultivation he must look after that unless there are others in his family capable of doing so. If he supports himself wholly or partly by labour, he cannot afford to abandon his labour during the months in which he must be watching his *tasar*. Indeed some said that they would cultivate if they could get advances to keep them while waiting for their profits. With the increased cost of living and the rise in the value of agricultural produce and agricultural wages this cause is operating with more force than formerly. More attention is now being given to cultivation and to the more valuable crops like chillies. Poultry-keeping has increased very much in recent years and a man can take to this without neglecting his other work. The same is true in a lesser degree of the keeping of cattle and sheep. There is also work in the mines and in the Sakchi iron works. There is a growing practice of buying up one or two rupees worth of tobacco in the town and hawking it about the villages. Enquiries made from one or two persons who were doing this elicited the fact that they formerly cultivated *tasar* but had given it up as they found this petty hawking more profitable. The fact that this occupation stands on the same footing as *tasar* rearing illustrates the position of the latter in the estimation of the Ho, and also that what is wanted by the class of people who usually cultivate *tasar* is small profits and quick returns. The first point to be grasped is that a man who is well-off will not be bothered to do *tasar*, a man who is living from hand to mouth cannot afford to do it because he cannot wait for his money, between these two comes the class who have enough but to whom a small addition to their incomes is welcome and these are taking to less precarious alternatives. In my opinion and in the opinion of others whom I have consulted, this is the most important factor in the decline.

Another reason generally given is the reduction in the number of *asan* trees. It must be remembered that in Singhbhum the Ho puts the worms on trees about his fields and not in the jungle. These have been cut for fuel or to sell the bark for tanning. With the extension of cultivation they are not replaced to the same extent as formerly. This, however, does not appear to be of much importance—were *tasar* rearing popular, means would be found to protect and propagate the *asan* trees, and the reduction in the number of these trees is a symptom of the decline rather than the cause of it.

A third factor is the difficulty of getting seed. The reserved forests are closed altogether and in the protected forests the monopoly of purchasing the wild cocoon has been given to one man for some years. At first he paid Rs 900 for it but the amount tendered has decreased annually and this year he pays only Rs 355. There seems reason to believe that the lessee has damaged his business by his own exactions, but in any case the shortage of seed is now met by importing a seed-cocoon from Hazaribagh which under-sells the local article. The local wild seed may cost as much as 2 pice the cocoon or 32 to the rupee, though this appears an outside price, the ordinary price is about 60 to the rupee while imported Giridih seed sells at 80. Some villages have given up the use of the wild seed altogether. Others get it from the Feudatory States surrounding Singhbhum from as much as twenty miles distance. This shortage of seed is certainly a factor in the decline in the Kolan, but its importance has been over-estimated. Wild seed is obtainable from the surrounding Feudatory States if the trouble is taken to fetch it and the small royalty paid. Villagers from villages which still use the wild seed pass on their way to fetch it through villages where domesticated seed only is used, and it is obvious that these latter use the domesticated seed through laziness or lack of enterprise rather than from sheer necessity. The ruling economic factor is, as stated above, the value of the rearer's own time and labour.

SAMBALPUR

7 Although Sambalpur is not included in the districts to which the enquiry refers, I visited the town of Sambalpur to obtain some information by way of corroboration from the weavers. *Tasar* is here known as *kosa*. The seed is collected in May by Kols and others who are residents of the jungle villages. These cocoons are sold at one or two to the pice to Gondas who are the principal rearers. The cocoons are tied up to trees in June or July, one or two to a tree. Early in July the moths eclose and the males are allowed to go, but the females are kept. When the females lay, the eggs are collected, rubbed between the hands to clean them (*Rannu* root is not used as in Singhbhum), and kept in *chhar* tree leaves. When the caterpillars hatch out, jungle shrubs are cleared from round the *sahaj* tree and the worms are placed on it. They go through four "jogs" and then form the cocoons of commerce. There is only one life cycle. There are two kinds of cocoons—*sankosa* (small) and *barkosa* (large). The former are collected in Asvin at the time of Dasahra and the latter in Kartik. There appears to be no difference between them except in the duration of the process and they are stated to be the same as the *laryas* of Singhbhum. The *barkosa* can be kept for rearing but the *sankosa* cannot. It is denied that the cocoon degenerates under domestication. The rearing is done by a particular caste, the Gondas who are also criminals and chaukidars. Some were interviewed at a chaukidari parade. The rearing is done purely to meet a local demand and there is no export. The supply is insufficient and the weavers import cocoons from Chakradharpur and Giridih. The rearers sell direct to the weavers (*kostas*) and there is no middleman. Cocoons are generally sold by the thousand and the Chai-bassa *kahan* is almost unknown. Twenty years ago they were selling at 240—200 to the rupee or Rs 5 a thousand. Now they are up to Rs 7 a thousand or above that. The deficiency is met by import and the local demand has decreased, so that prices have not risen in proportion to the shortage of the local supply. The reasons given for the failure of supply are much the same as in Singhbhum, viz, (a) the precarious and gambling nature of the business "Helata *tasar*, na hela *khassar*" (*i e*, a venture in the business means either *tasar* or ruin), and (b) reservation of the forests. Within the last few years there has been some extension of the area of forest reserved in the Sadr thana, and all Gondas in this thana have given up *tasar* now. In this district I learn that Messrs Bros Partners & Co of London buy up the waste silk (*i e*, the coarse part of the cocoon which is cast aside by the twistors) at 3½ seers to the rupee and send it home, and it comes out again as yarn. So no part of the cocoon is wasted.

MANBHUM

8 Weaving is much more important than rearing in the Manbhum district. The weavers are suffering much as a result of the shortage of cocoons and the rise in the price of them. Many in Raghunathpur have abandoned *tasar* for cotton. There is no doubt that they would benefit considerably by increased production of cocoons which would enable them to manufacture *tasar* cloth at a cost which would not bring it into competition with the pure silk products. The weavers depend, and have always depended, chiefly on Chaibassa cocoons and only supplement them with the local article which is inferior in quality, as the output has always been comparatively small in quantity. At present about 2,000 to 3,000 *kahans* are obtained by the *mahajans* from Barabhum and neighbouring places during the year and the average turn-over annually is about Rs 18,000. Formerly as much as this used to be obtained in the neighbourhood of Purulia alone. There is a small export to Bankura and Birbhum. The chief area of *tasar* rearing is within an area of four or five miles about Kenda on the Manbazar road. In Kenda itself about 30 persons were doing *tasar* last year whereas ten years ago the number was more like 50, and was perhaps 80 or 90 twenty years ago. The supply from this village was between 40 and 50 *kahans* last year whereas twenty years ago it often amounted to 200 or 300 *kahans*. The total number of rearers in this area may be put down as varying from 200 to 300 and the average output at present as from 1,200 to 1,500 *kahans*.

As the Manbhum cocoon is not highly appreciated by weavers and only used when better cannot be obtained, the prices have not risen much with the shortage. The rearers say that they receive Rs 5 to Rs 7 a *kahan* according to demand, but a *mahajan* of Purulia says that recently he has paid as much as Rs 8 or Rs 9. There is a story that the price once rose to Rs 20 a *kahan* owing to a sudden and heavy demand. It would, however, be impossible to manufacture *tasar* profitably with cocoons at this price, and if the story is true, it must have been a very exceptional condition of affairs due to weavers being bound to execute orders already placed. The rearers deny that there has been any material variation in prices during the last twenty years. It is obvious, however, that with the rise in the price of food-stuffs *tasar* bringing in the same income as it did twenty years ago is less profitable now. The rearers, however, ascribe the decline to other causes as in Singhbhum, *viz*, (a) deforestation and lack of money to purchase seed cocoons from other places, (b) the increased attention to cultivation and the fact that, unless a man has food-stocks, he cannot afford the time to rear *tasar*, (c) the precarious and irksome nature of the business and the austerities dictated by religion which lead the rearer to drop this casual occupation and to take to others equally profitable and less troublesome. Among these may be included the cultivation of lac the prices of which have risen very much.

Landlords, of course, attempt to make some profit for themselves out of the *tasar*. Formerly all cut cocoons were the perquisite of the landlord, but it was found that the rearers disposed of these *phukhas* by stealth and the landlord took Re 1 per *ara* instead. He further claims one cocoon per *pan* of outturn but the rearers contest this. It does not appear that such small impositions have any influence in discouraging the rearing of *tasar*. The condition of the cocoon depends very much on the weather, but it is denied that there is any deterioration.

HAZARIBAGH

9 *The trade and prices*—From information received in various places, I was prepared to find that the trade done in cocoons in Giridih is larger than generally supposed, but the facts stated by the *mahajans*' servants came somewhat as a surprise. If they are to be believed, the trade done here is at least equal to that done in Singhbhum and perhaps larger. Singhbhum has the advantage of producing a better cocoon and of proximity to the western market, but Giridih taps a larger area of country. In some matters, however, the information seems unreliable. The *mahajans* did not appear them-

selves but sent their servants and after some hours spent in cross-questioning there, it became apparent that on many points they were giving deliberately false information. There is evidently a ring of *mahajans* here who make their profits by queering the market and are interested in suppressing the true state of affairs. At last one man appeared who failed some time ago and at present has a very petty interest in *tasar*. His statement may be accepted as reliable and contradicted those of the others on several material points.

The facts seem to be that for some twenty or thirty years there were only two firms trading here, *viz*, Messrs Payen et Cie and Jagannath Ram. The former took three quarters of the demand and (as I learned in the villages) paid a fair price for it. But they retired and Jagannath Ram failed. Their place was taken by many dealers on a smaller scale. The shrinkage in the demand caused by the retirement of Messrs Payen et Cie caused a large shrinkage in the supply, and though the demand has in a considerable measure recovered and Giridih is now supplying the Western market, the supply has not recovered in the same proportion. The present dealers do not stock cocoons but act entirely as brokers. The *Parikar* goes round the villages and buys from Sonthals and others who rear *tasar*. He is said by the villagers to "loot" them, especially those who produce only a few *pans*, and he pays at the rate of perhaps Rs 6 only for a *khar* of *mugas* that he may sell at anything from Rs 9 to Rs 14 and perhaps less than Rs 3 for *laryas* that may fetch Rs 6 or Rs 7 in the market at Giridih. The rearers are for the most part aboriginals who are afraid to go into the markets. Even when they do so the *Parikar* still steps between them and the buyers. The *Parikar*, not infrequently it is said, sorts over the cocoons, rejects some and demands others in their place and then takes the rejected cocoons for nothing. A Marwari (*Parikar*) at Gande pays his fellow caste men better prices than he pays to others—a clear indication that it is the will of the dealer and not the state of the market that fixes the price paid to the rearers and that there is scope for paying a higher price without loss to the purchasers. There is a further middleman, the broker who sells the *Parikar's* cocoons to customers and receives anna 1 per *khar* from each party for doing it. The agents of Messrs Payen et Cie used to buy direct from rearers to a large extent. Their system was to take sixteen cocoons from a *khar* selected to represent the whole (the cocoons placed on the Giridih market are mixed) and after the chrysalis had been cut from these, they were weighed and payment made at known rates accordingly. The rearer is getting less and the dealer more for his cocoons than formerly.

10 *Other causes of decline*—In this matter the story told here is much the same as that told elsewhere. In the first village visited, Kalyanpur, the first man met said that he had done *tasar* last year, but had not done it this year, as there was no other person in his household to look after the cultivation of the land and he could not spare the time. The next man questioned was watching his *tasar* on the trees, and said that he was doing less this year than last year because his search for seed had been unsuccessful. He attributed this to the great heat and short rainfall last year. Other places were visited but most information was obtained in Mohanpur. It appears that here only one crop is raised for the market, *viz*, the *barsati* crop, and the *jadur* crop is unknown. No seed is kept from year to year but it is sought in the jungles in July and August. *Laryas* are used for breeding, but the *mugas* are sold off as they eclose uncertainly. When the moth comes out the males are allowed to go and the females are put outside for the night, when they are visited by the males and begin to lay at once. In eight or nine days the eggs hatch, the caterpillars are put on the trees, and then the trouble begins. Constant vigilance is required, and unless a man can afford the time, or has relatives who can look after the more important business of tilling the soil, the two months of watching is impossible. In any case he must be of an industrious character to undertake it. The *tasar*-rearer "does not do it for his food but for the salt with his food," and a lazy man will prefer to go without the salt. Some two months elapse while the caterpillar changes its skin four times and then spins itself in and forms the cocoon of commerce. This is the period of risk. Besides the depredations of birds there are the chances of

the seasons. A dry season may mean the loss of the whole crop. The villagers about here state that *laya* seed may give some *muga* cocoons and *muga* might give some *laya* cocoons, and it much depends on the weather in September which kind of cocoon is produced. I do not know whether this is a scientific fact. There are further the risks from disease of which they recognise three—*chherua*, *larka* and *marh*. It was in this village also that the chief complaints against the dealers were made. It is not surprising that as he labours under these many disadvantages the villager is always ready to abandon *tasar* for anything else that offers better prospects, for instance, a large amount of *tasar* was formerly reared about Gajhandi in this district, but it has been abandoned for work in the mines.

As in other places, no evidence can be found here that the cocoon has on the whole degenerated in quality.

RANCHI AND PALAMAU

11 As far as my enquiries go there is very little *tasar* rearing still left in Ranchi and no villages in the district were visited. At one time Palamau used to supply cocoons to the weavers of the Anrangabad subdivision of Gaya, but the weaving industry there has practically ceased. Owing to the very limited time at my disposal Palamau could not be visited.

SONTHAL PARGANNAHS

12 *General*—The industry in this district is a jungle industry. Cultivation is carried on in the small jungle surrounding the villages and not actually in the fields as in Singhbhum. The rearers are Sonthals and Paharias in the Damin-i-Koh and Khetarias, Bhuiyas, Goalas, Kewats and Parighas in the jungles of the zamindari tracts. The subdivisions of Rajmahal, Godda, and Pakaur are the most important areas for *tasar*.

13 *The method of rearing and the crops*—The Sonthals in the Damin-i-Koh used both wild and domesticated seed elsewhere seed cocoons are generally preserved from the previous year's crop. The actual process is much the same as elsewhere. The insect passes through the usual metamorphoses and there are two crops, one about the end of September called by Sonthals and Paharias *barsali* or *barsati* and by others the *bhador* crop. There is also a *jadui* crop in December or January. The former crop is small, but it is of the best quality, the latter is very abundant but sells at a much lower rate. The former crop is, I think, being largely abandoned, as in the places where I made enquiries only the *jadui* crop was known. In Hiranpur and Tinpahar markets of this district and in Bhagalpur, the persons examined spoke only of a winter crop from the Sonthal Pargannas.

14 *The number of persons engaged in rearing tasar in this district*—This is here as elsewhere very difficult to estimate. At Katikund I was told that it is done in eight or ten villages of the Gopi Bungalow, three or four villages in the Narganj Bungalow and ten or twelve villages in the Katikund Bungalow. In each village three or four families take it up. These three bungalows belong to the Dumka Damin and the figures indicate that roughly 300 persons are rearing *tasar*. This would mean at the same rate 1,200 persons in the whole Damin-i-Koh. But the cultivation is much greater in the direction of Salubganj. The average output of each rearer is said by the Sonthals of Katikund to be about 30 *pans* or, say, 2 *kahans*. In Tinpahar market the residents say that some bring cocoons in handfuls and some in sackfuls and it is impossible to obtain any idea of the average amount of cocoons brought by each person. Accepting Rs 4 as the average selling price and Rs 25,000 as the average turn-over in Tinpahar bazar, the result is 6,250 *kahans* or 3,125 rearers. But probably where more people rear *tasar* they also do it on a somewhat larger scale, and this figure may be reduced, and it is probably safe to estimate the number of rearers in the Damin in any year as about 3,000. An estimate made independently of mine gives 3,000 for the Damin and the same number for the zamindari tracts or 6,000 for the whole district.

15 *Trade and prices*—Some thirty years ago a European firm of which the name is doubtful used to send an agent to camp in Tinpahar bazar and buy cocoons. It has been suggested that he was an agent of Messrs Newcomer & Co., but some of the villagers in Tinpahar spoke of him as "Dibru Sahib" which makes it possible that he was Mr Jules Deveria of Rampur Boahia who is mentioned in Watt's "Economic Products of India" as doing a large business in *tasar*. However, the point is not important. Since this European firm ceased to buy, the amount of the produce has been decreasing. In Singhbhum with the decreasing supply prices have, as might be expected, been rising, but the Sonthal Pargannahs cocoons appear to have an independent market and are not affected by the large demands of the Central Provinces market, nor do they enter into competition with the superior Singhbhum cocoons. There may be occasionally inflated prices owing to sudden and unexpected demands, but on the whole the prices received by the rearers in the Sonthal Pargannahs are falling. The rearers in the Damin-i-Koh used to pay a tax to Government for *tasar*-rearing. This was remitted at the time of the last settlement, and though the slump had already set in, the removal of the tax gave a certain impetus to the industry. About ten years ago the rearers used to receive ₹6 and ₹7 a *kahan*. Rupees 4 was once considered a really bad price. But a few years ago the Forest Department appointed certain "licensedars" and gave them a monopoly of the right to buy *tasar* cocoons. These "licensedars" have formed a ring and give what price they like for the *tasar* and naturally give an absurdly low price. They pay ₹1 for their license and annas 6 tax per *kahan* to the lessees of the market in which they purchase. They insist on having cocoons at 8 *pans* to the rupee or ₹2 a *kahan*. It is marvellous that this sickly industry should survive at all under such disabilities, but no one is dependent on *tasar*. A man uses his surplus time and energy to add a little to his income by this means and looks on anything he makes, however small, as profit and therefore he is content to go on doing it.

The annual value of the trade to the district is estimated at ₹80,000, distributed as follows among the subdivisions—Raismahal ₹25,000, Pakur ₹16,000, Godda ₹25,000 and Dumka ₹14,000. These figures exclude Jamtara, where some weaving is done, but no enquiries about rearing have been made. Most of this money goes into the pockets of the middleman, at least in the Damin. In the zamindari tracts the rearer has to pay a cess which varies from ₹1 to ₹1-8 per *ara*. He has nothing else to pay and gets better prices from the "Paikar," last year he received ₹1 for 3 *pans* of the *jadui* crop. The market rate when produce is abundant is ₹6 per *kahan* for *muqa*, ₹3 for *lenga* or *larya*, and ₹1-8 for *phukha*. At present before this year's produce is on the market the rates are ₹14, ₹6 and ₹4, respectively. *Phukhas* were selling at ₹2-8 in the Hiranpur market at the time of my visit. I was informed in Bhagalpur that ₹5 to ₹7 was the ordinary rate to pay for Sonthal Pargannahs cold weather produce according to quality. The Bhagalpur dealers visit Tinpahar mart in person and there is no middleman except the "licensedar" or "paikar." The former is making an unfair profit at the expense of the rearer.

16 *Other causes for the decline of tasar rearing*—The monopoly of "licensedars" by itself would be enough to account for the decline within the last few years in the Damin, but *tasar* rearing was declining before the "licensedar" came and it is declining elsewhere also. It is, therefore, necessary to look for other causes. The chief cause of decline originally was the reservation and protection of the forests. The caterpillar was previously reared on *asan* trees in the jungle, now it is reared on the patches of forest bordering on the village. The number of trees is insufficient as, even if they are not cut for fuel a tree is almost completely destroyed by worms in one season. To obtain fresh shoots on the same trees they are pollarded; and from feeding entirely on new leaves the worms get a disease *chhirai* (Chherua or Cholera) and die off in large numbers. There is another disease *angaria* in which the worm turns black "like coal." It is attributed to always cultivating the *tasar* on the same spot, though its nature is not understood. The semi-domesticated moth (*i.e.*, those cocoons kept from the previous crop) is

more liable to disease than that from the wild seed of the jungle; and as the closing of the forest has made it increasingly difficult to obtain wild seed, the proportion of domesticated seed is greater than it was. There is the same story as in other districts of the risks and trouble involved in the business. It is only done by those who have a little time to spare from agriculture and a little spare cash for seed. If any alternative occupation is offered, *tasar* is gladly abandoned for it. The people have now largely taken to lac which is far more paying. Many also are employed in stone quarries and ballasting work on the Railway in the Rajmahal and Pakaur subdivisions.

17 The question propounded in Mr Maxwell Lefroy's note can now be answered. In the previous notes each district has been treated separately because conditions varied so much that it was difficult to write a combined note.

(a) *Is there any shortage in the supply of cocoons?*—Yes, the supply is this year very considerably short of the demand and this is the usual state of affairs. But at the same time the demand is irregular and uncertain.

(b) *Is this due to low prices?*—Conditions vary very much from district to district; the *tasar* itself as put on the market is not a uniform product, and it is very difficult to ascertain rates. Further, the enquiry was made before the rearer was putting his *tasar* on the market and it was necessary to depend on oral, and sometimes deliberately incorrect, information. But the fact seems to be that in Singhbhum the rearer is getting the advantage of the enhanced prices, but the price of *tasar* has not increased in the same ratio as the price of staple food crops and *tasar* rearing from this point of view only is less profitable than it was. In Hazaribagh the rearer is robbed by the middleman, and in the Sonthal Pargannahs he is the victim of the monopolist. The bad prices received are one factor in the decline.

(c) *Is there any distress or poverty consequent on this?*—Most certainly not, among the rearers. Among the weavers, with whom this note is not concerned, there is reported to be a certain amount of distress from the shortage of cocoons and the enhanced cost of them. But the rearer is not and never has been even partially dependent on *tasar*. It is essentially an occasional occupation for his surplus time and energy by which he may make a welcome addition to his income, but by which he never looked to live. If all *tasar* rearing could be stopped to-morrow, no one would go hungry by reason of it. The idea that it is necessary to revive the *tasar* industry in order to save the rearer from want is a mistake.

In this connection it may be noted that the estimate of the number of people in the province engaged in rearing *tasar* as 100,000 is, in my opinion, very wide of the mark. The number fluctuates and the same people do not do it every year. I have given reasons for fixing the maximum at 10,000 in Singhbhum (which is the chief centre of the industry), 6,000 in the Sonthal Pargannahs and perhaps 1,000 in Manbhum. In Hazaribagh the only fact on which any guess can be based is that the trade is about equal to that of Singhbhum. But if 10,000 is added for this it will include many of the Sonthal Pargannahs and Manbhum rearers. If we reduce it to 7,000 it gives a total of 25,000 rearers who sell through the most important marts. The few rearers of Ranchi and Palamau still remain to be counted and the industry is not altogether dead in Gaya and South Monghyr. There is also a very little done in some of the Orissa districts. The figures already given are maxima and in my opinion the number of rearers in the whole province in any year cannot exceed 30,000.

(d) *Would improved cocoon production be beneficial or is it not needed?*—The cry is for increased not improved production, and that comes from the weavers. Neither improved nor increased production is needed in the sense that it is necessary to save the rearer from want. Improved production might mean the production of a cocoon that would eclose regularly and not be liable to disease and thus would remove certain elements of risk, but it could not guarantee the seasons or scare away the kites. *Tasar* rearing must under any circumstances be a precarious undertaking and not one to which a man could look for his livelihood. I cannot find any evidence for

the supposed deterioration of the cocoon as a silk-producer. Moreover, in the present uncertain and disorganized state of the *tasar* market, an expensive enquiry which may or may not be successful and the very purpose of which is not altogether clearly defined, would be a waste of money. Certain unjust disabilities from which the *tasar* rearer suffers should, if possible, be removed, and when it has been ascertained what power of recuperation the industry has within itself, it will be time enough to undertake scientific enquiries for the purpose of improving the breed of the moth.

(e) *Has the rearer given up because he prefers to or because he must?*—The rearer is abandoning *tasar* because he is finding more profitable and less precarious methods of employing his surplus time and energy. This question is answered throughout this note.

(f) *Is the decrease in production due to the increase in value of rice and the increase in wages, leading rearers to abandon the less profitable *tasar*, or to inability to get good stock to rear from and good results from rearing?*—The increased cost of living and the rise in the money value of agricultural produce means that increased attention is being given to agriculture, and the cultivator has less spare time and money to spend on *tasar*. The rise in the wages paid to labourers is, of course, only one aspect of the increased cost of living, in any case it must be remembered that a man who lives by daily labour cannot do *tasar*, for he has not the means of living while he is engaged upon it. This is the reason why agricultural scarcity is always followed by a setback in *tasar* rearing. Enquiries show that this is the most important factor. There is more difficulty than formerly about getting seed, and this is one among many things which go to make *tasar* unpopular and lead the rayat to take to other kinds of employment if they are open to him.

(g) *Finally, is the decrease due to the Forest Department restricting areas in which rearing can be done?*—The decrease is largely due to the reservation or destruction of the jungles, especially in districts like Sambalpur and the Sonthal Pargannahs where the industry is mainly a jungle industry. But throwing open of the whole of the reserved forests would not, I think, result in restoring the industry to its former position, because the rise in the cost of living and the increased economic value of a man's time and labour, making the petty earnings from *tasar* of less worth than formerly, are more potent factors in the decline.

18 *General summary*—Conditions vary much from place to place and there seems no organized market to produce uniformity. The demand was probably more regular and certain when European firms were trading, though the Central Provinces market has largely taken their place and its demands usually exceed the available supply, the market is on the whole irregular and uncertain and does not encourage systematized rearing. *Tasar* rearing has never been an industry on which any one depended for a living, it is occasional occupation in which a constantly fluctuating number of persons invest their surplus time and energy. If anything more profitable and less irksome and precarious presents itself, *tasar* is dropped without regret. Even in a good year the value of the output of a single rearer is small, over a series of years owing to the risks of the business the profits are negligible. It is worth doing as long as it does not interfere with anything else, and while the time not spent on it would be lost, but the increased cost of living and consequently increased value of a man's time and labour, and the other avenues of employment which are opening, make *tasar* rearing year by year of less account.

Weavers and dealers interested in the increased production of *tasar* urge that advances of money should be given to the rayats to enable them to tide over the two or three months while the *tasar* is on the trees. In the present state of the *tasar* market I think it would be unwise to attempt to stimulate production at all, and to stimulate it by advances would be a disastrous mistake. The *tasar* is too precarious to secure a loan, and it would certainly mean mortgaging land for the sake of the *tasar*, and in the end heavy indebtedness and loss of the land. The *tasar* is not worth it.

At the same time I think that something should be done to remove obstacles from the way of those who still wish to do *tasar* (and they are fairly numerous) and to enable them to get the fair market price for their produce. The rearers are mostly jungle folk and the jungle produce is their birth right. It ought to be possible to give them permits to go into the reserved forests to search for seed. In districts where rearing is done in the jungles, an area of *asan* trees might be set apart in the protected forests for the purpose and divided into four blocks. One block could be used each year and have three years' rest. The trees would not suffer from *tasar*-rearing on them once in four years. The Forest Department should not look to make any profit out of *tasar*. If it is necessary to exercise control over the purchasers of forest produce, at least a sufficient number of licenses should be granted to ensure competition. Monopolies of the right of purchase given to one or two persons constitute a grave injustice to the rearers. There might also be room for co-operative selling. The difficulty in this is that the rearers are different persons from year to year, the number doing *tasar* in any one village is small and the output of each man is very small, a society to be large enough to employ their own agent in the market would have to embrace a great number of villages. Co-operative credit for the purpose of financing production could not be recommended, because the *tasar* is too precarious a crop to afford security for a loan.

JOHN R. DAIN,

*Offg. Director of Agriculture,
Bihar and Orissa*

RANCHI

The 28th September 1916

APPENDIX A

Ampatia —The first or seed crop consisting of flimsy cocoons

Angaria —A disease in which the worm turns black

Ara —(1) The area where cocoons are reared, (2) the license to grow cocoons there, (3) generally cocoon rearing, "bura ara," the chief crop

Asan —The tree on which *tasar* is chiefly reared (*terminalia tomentosa*)

Banala —Barra

Barkosa —The large cocoon of Sambalpur

Barra —Wild *mugas* that cut first year and pierced cocoons of same

Boga —The caterpillar after the fourth casting of its skin. There is no particular name for it in the previous stages (Sambalpur)

Boiki —A particular disease of the moth

Bugui —A kind of cocoon obtained from *mugas* at the end of the cold weather

Chhar —A tree the leaves of which are used to wrap the eggs

Chherina —A disease somewhat like cholera

Chharai —Chherina

Daba —The domesticated cocoon. It is called "jata daba" in its first year of domestication

Dhulia or *dhuria* —Cocoons of the *ampatia* crop

Guti —A common word for cocoon

Hagiri —Is chherina

Jata daba —See daba

Jadui —The winter crop

Kahan —A measure—

4 cocoons	.	.	1 <i>ganda</i> .
20 <i>gandas</i>	.	.	1 <i>pan</i> (80 cocoons)
16 <i>pans</i>	.	.	1 <i>kahan</i> (1,280 cocoons)

but the *kahan* is sometimes taken as 1,300

Khari —Is the same as *kahan*

Koa —A common word for cocoon

Kosa —Used in Sambalpur for *tasar*.

Larka —A disease of *tasar*—*Meshia*

Larya —A somewhat soft cocoon with a long stalk Found wild

Lenga —Is the same as *larya*

Lumam —Santali for *tasar*

Meshia —A disease of *tasar*-*larka* (?)—"angaria"

Muda —*Muga* cocoons which have not eclosed during the first year

Muga —(1) The large, hard, wild cocoon, (2) any large and hard cocoon

Murli —A disease (?) the same as "angaria" (see Mukharji's report, page 7)

Narya —Is the same as *larya*?

Pagala —A colloquial term applied to a cocoon fixed close to the branch without a stalk and more nearly spherical than the ordinary cocoon It is rejected by dealers (Giridih)

Pan —See *kahan*

Path Muga —Another name for wild *laryas*

Pukha —A "blown" cocoon from which moth has eclosed

Raksata —Pierced cocoons of the *larya* crop (Giridih)

Rannu —A root used to rub the eggs of the moth to hasten hatching

Sahaj —Is the *asan* tree (Sambalpur)

Sankosa —The small cocoon of Sambalpur

Sarhan —A term used by dealers in the Sonthal Pargannahs for a mixed lot of cocoons

Tira.—A small *muga* cocoon The Sonthals say it is the cocoon of the male while the large *muga* is the cocoon of the female (*patni*)

APPENDIX B

Dalkati figures from the Kolhan

Year.	Realization*	Rearers	Year
1	2	3	4
	Rs.		
1908-09	5,712	7,616	1907-08
1909-10	5,895	7,193	1908-09
1910-11	5,395	7,193	1909-10
1911-12	4,488	5,984	1910-11
1912-13	6,000	5,000	1911-12
1913-14	5,807	7,742	1912-13
1914-15	7,790	10,387	1913-14
1915-16	5,760	7,680	1914-15

The *dalkati* is a tax of Rs 1 on those who take *ara* The first two columns are taken from the Budget estimates for the year indicated, the figure

in the estimate being the actual realizations of the previous year. Possibly this system was not consistently followed, as the second and third items are identical and Rs6,000 in 1912 looks like a round figure. Figures for years previous to 1908 were not obtainable, as the *dalkati* was then lumped together with other miscellaneous receipts. The Government receive only annas 12 of the *dalkati* tax and therefore the figure is multiplied by 4—3 (in column 3) to give the number of rearers in the year noted in column 4. Further, if the crop of any cultivator is an entire failure, *dalkati* is remitted. Something therefore has to be added to these figures for total failures but it will be on a sliding scale, for it is probable that the larger the number of successful rearers who paid, the better must have been the crop and the lower the ratio of failures to successes. In my opinion 8,000 should be taken as about the normal number of rearers in the Kolhan. The figure 10,387 is exceptional and probably due to a temporary impetus given to the industry by high prices in the previous year (*vide* paragraph 5).

APPENDIX C

Statement of cocoons despatched from Chakradharpur station during the years 1912-15, in maunds

Month	1912	1913	1914	1915
1	2	3	4	5
January	402	640	966	344
February	<i>Nil</i>	454	863	343
March	<i>Nil</i>	207	308	33
April	<i>Nil</i>	53	105	<i>Nil</i>
May	<i>Nil</i>	<i>Nil</i>	68	<i>Nil</i>
June	<i>Nil</i>	47	93	<i>Nil</i>
July	<i>Nil</i>	41	69	<i>Nil</i>
August	12	29	9	<i>Nil</i>
September	<i>Nil</i>	<i>Nil</i>	<i>Nil</i>	<i>Nil</i>
October	331	184	396	480
November	3,185	2,027	2,131	2,619
December	1,381	1,291	1,492	1,769
	5,310	4,974	6,303	5,588

This statement was furnished to me by the courtesy of Bengal-Nagpur Railway Company. It will be noted that in August and September, the time during which the enquiry was made, *tasar* is not coming on to the market. Further, it will be noted that the export fluctuates considerably. It would have been interesting to have obtained a similar statement for Giridih and other stations in Hazaribagh, but the enquiry there was undertaken late and there was no time to obtain it before submitting this report.

APPENDIX XV.

TRADE IN BURMA.

TABLES

FRONTIER TRADE

Raw Silk

The figures of imports and exports of raw silk and piece-goods are abstracted from Reports on the Transfrontier Trade of Burma for the years 1913, 1914 and 1915. There is a small export (100 maunds) of raw silk to the Southern Shan States and North Siam; there is a larger import (2,500 maunds) from West China; little from the Southern Shan States; it has fluctuated singularly little, perhaps as the war has not affected transport; only the export in 1914-15 fell notably.

The import from West China is important; it is worth remembering that this pays no import duty and that this has been a bonus of 5 per cent up to 1916, when it became $7\frac{1}{2}$ per cent; there has been a total loss of revenue of about three lakhs on the total imports of raw silk on the last five years.

Piece-goods—The imports were considerable, with a value of six to eight lakhs a year but this has fallen to under three; nearly all is from Siam. The exports have also fallen from seven lakhs a year to nearly four, but 1914-15 saw an export to the Southern Shan States worth $8\frac{1}{4}$ lakhs, which has fallen to two lakhs. The exports and imports of piece-goods about balance, but the imports are from Siam, the exports to the Shan States, so that the balance is against Burma.

Imports by sea

Eight tables are here reproduced, supplied by the Chief Collector of Customs, Rangoon

The first gives the imports of raw silk and piece-goods from foreign countries for ten years: China Hongkong and Straits Settlements (all China produce) are alone concerned in raw silk till 1911, when Siam comes in and the total fluctuates from ten lakhs in 1906 and 1915 to 31 lakhs in 1912-13. In piece-goods Japan leads with six million yards in 1906 and 1915, eleven million in 1912, China sends from three thousand to eighty-four thousand yards this last in 1915, Germany, Holland, Belgium, France, Austria, sent 150,000 yards in 1906, only 4,000 in 1913-14 and the United Kingdom has fluctuated from 235,000 yards in 1908 to 25,900 in 1910-11

The second gives foreign imports in detail the most interesting point is the importation of mixed silk fabrics from the United Kingdom there was a small import also of spun-silk (silk yarn) from Germany and Belgium

The third enumerates Coasting imports, of Indian merchandise the two interesting items are Indian piece-goods from Calcutta, Bombay, Madras and "provincial ports" (the last the biggest and presumably covering the Tavoy production) and the import from Madras of mixed piece-goods

The fourth table is of Coasting imports of foreign merchandise and the item of import of piece-goods of foreign manufacture from Provincial ports presumably covers importations of Siam silk fabrics through provincial ports

The fifth table of foreign exports of Indian merchandise is interesting chiefly as a record of an export of Chassam to the United Kingdom, fluctuating from four to twenty-eight thousand pounds weight

The sixth is of no great interest, the seventh shows the distribution of foreign raw silk, and piece-goods to provincial ports and the last the distribution similarly of Indian piece-goods chiefly of Burma production probably

APPENDIX XIX.

Order of the Austrian Minister of Commerce, dated June 24, 1904, concerning the subsidy granted to the silk reelers in Southern Tyrol and in the territory of Gorz and Gradiska

Considering the unfavourable economic conditions of silk spinning in Southern Tyrol and in the districts of Gorz and Gradiska and with a view to improving the position of the women employed in this industry this Ministry, in concert with the Ministries of the Interior and of Finance, conditional on the constitutional approval of the necessary funds devotes the sum of 150,000 kronen* per annum for five years, for the granting of subsidies

The conditions under which these subsidies will be granted to individual spinners are contained in the following articles and may be modified subsequently if found necessary

Article 1

The subsidies will be granted according to the number of basins at work, at the rate of 12 1/2 cents,† for every basin and for every quarter of a day's work up to a yearly maximum amount of 120 kronen per basin

In granting these subsidies, other conditions being equal, preference will be given to those basins tended by women belonging to the same silk district

As the whole subsidy may not exceed 150,000 fr, if applications by reelers entitled to receive subsidies should be so numerous as not to allow all of them being granted, preference will be given to those which were recently working

Reelers in receipt of subsidies are bound for the whole season of production to conform to the present regulations, also in the event of their output being above the quantity which entitles them to the maximum yearly subsidy

Article 2

Only those factories which conform to the provisions of the industrial regulations and are in a condition to work in all seasons may claim subsidies

Article 3

Only basins heated by steam and provided with mechanical reels constructed for reeling four or more threads and assisted by stirrers may be subsidized

Article 4

Basins constructed for spinning four or more threads will be subsidized even if they spin less than four threads, provided the weight per unit length spun be above 16 *denari* (one *denaro* corresponds to 0.05 grams per length of 450 metres)

Article 5

Every subsidized basin must be served by a woman who must not be employed at another basin

Article 6

The subsidy will be granted only to those basins which work at least 150 whole days per annum during the first three years and at least 180 whole days in the following years

* Kronen = 10 pence

† Cent = 1/4 of a penny

The industrial year will begin on June 1 and end on May 31 of the following year

Basins which start work in the course of the season may also apply for subsidy for the time up to the beginning of the next season provided they work at least for a period equal to half the number of work days in this period

Article 7

Reelers in receipt of subsidies engage to adopt the following minimum scale of wages —

- (a) Head reelers, 10 cents per hour
- (b) Sub-headed reelers 9 cents per hour
- (c) Experienced stirrers and apprentice reelers 8 cents per hour
- (d) Young stirrers 7 cents per hour
- (e) Apprentices during the first year 6 cents per hour
- (f) Beginners during the first six months 5 cents per hour

As a rule no workwoman may remain more than one year in any of the four lower classes *b—e*

Reelers must keep to the maximum of 11 hours work per day as fixed by the industrial regulations for factory work, they have no right to avail themselves of the provisions of the Ministerial despatch No 16175 of May 23, 1886, according to which reelers are allowed, on special request, to work 13 hours a day for a period up to 8 months

Article 8

Reelers who apply for a subsidy must state in their applications to the proper industrial authorities the number of basins which will be worked, and the approximate number of women employed, they must also send in a copy of the regulations of their factory. The said authorities, who may meanwhile consult trustworthy and competent persons, will then forward, through the provincial political authorities, their proposals to the Ministry of Commerce. The decision of the latter is sent directly to the industrial authorities and notice of it is forwarded to the provincial political authorities

Article 9

Reelers who have presented their application for a subsidy must inform the industrial authorities as early as possible of the date on which they will begin to work and they must notify them also of every suspension or interruption of work, Sundays and holidays excepted. Such notice must possibly be sent in advance, and at latest within 24 hours

Article 10

For the purpose of surveillance every factory must keep the following books —

- (a) A daybook showing—
 - the numbers of basins in daily use,
 - the output of each basin per day expressed in whole days or in quarters of a day,
 - the quantity of cocoons consumed by each basin and of the reeled silk, also its weight per unit length (titolo)

The reelers are free to add further data as they may consider opportune for their factories

- (b) A register of the wages compiled exactly in accordance with the Form A

(c) A pay book for each workwoman, kept in accordance with Form B

(d) A register for the inscription of the result of the inspection by the official charged with the inspection of the factory

The payment of the wages of the workwomen to be made every 14 days

At the beginning of each fortnight the workwomen shall deposit their pay books with the reeler

Workwomen not complying with the last-mentioned conditions are not to be allowed to work. The output of work of each workwoman during the fortnight (including quarter days) shall be registered in the pay book and the books shall be returned to the workwoman at the end of each fortnight with the calculated quantity of wages entered and at the same time payment shall be made for the said period

All books including registers relating to the work of reeling except commercial books, shall be presented on request to the authority charged with the inspection which shall have free access to the workrooms at any time

Not later than the 5th of each month, there shall be consigned to the industrial authority a report of the basins in use each day during the preceding month

Article 11

The officials charged with carrying out the provisions of this ordinance shall be presented to the reelers by the industrial authorities

Article 12

The awarding of the bounties will take place at the end of each six working months

The reelers having the right to the bounties shall present through the channel of the industrial authority concerned an application provided with proper documents, with the name of the office at which payment is to be made, and drawn up so as to obtain settlement of the subsidy. The industrial authority on the basis of the monthly reports (Article 10, last paragraph) and the revisions made on the spot, shall fix the corresponding amounts of subsidy and after again consulting with reliable persons competent in the matter, eventually consign the application with relative proposals, through the provincial political authority to the Ministry of Commerce

The award of the bounties by the Ministry of Commerce is made through the channel of the provincial political authority

Article 13

In case of abuse of any of the provisions of this law the subsidies shall be temporarily or absolutely suspended, and the offenders shall be liable to the consequences of the common law. These provisions shall come into force immediately

IV

Decree of the Imperial and Royal Ministry of Commerce modifying Article 1 of the provisions of June 24, 1904, concerning the subsidies to Silk Reelers of the Southern Tyrol, Gorz and Gradiska

In agreement with the Ministry of the Interior and Finance the provisions of paragraph 1 of Article 1 of the decree of June 24, 1904, concerning the subsidies to silk reelers of Southern Tyrol, Gorz and Gradiska are modified as follows —

(1st paragraph of Article 1.)

The subsidies shall be granted on the basis of the number of basins at work and at the rate of 11 5 hellers* for every basin and for every quarter of a day's work up to a maximum of 135 fr for every basin

* Heller = $\frac{1}{10}$ of a penny

This provision will be considered as having come into force on June 1,
1905

*Loi relative aux encouragements spéciaux à donner à la sériciculture et à la
filature de la soie. (Loi du 11 juin 1909.)*

Le Sénat et la Chambre des Députés ont adopté

Le Président de la République promulgue la loi dont la teneur suit.

Article 1.

A partir du 31 mai 1909, jusqu'au 31 décembre 1929, il sera alloué aux sériciculteurs une prime de soixante centimes (0 fr 60) par kilogramme de cocons frais, qu'ils soient destinés à la filature ou au grainage.

Article 2

Dans chacun des départements séricicoles, il sera institué, par les soins du préfet, une commission de contrôle des primes à la sériciculture.

Pour faciliter le contrôle de cette commission, les emballages immédiats contenant des graines de vers à soie devront, au moment de la vente et de la mise en vente, porter sur une banderole de fermeture, en caractères connus et apparents, le nom et l'adresse soit du producteur, soit du vendeur ainsi que l'indication, exprimée en grammes, du poids net des graines de vers à soie qu'ils contiennent avec une tolérance maximum de cinq pour cent.

Un décret rendu sur le rapport du Ministre de l'Agriculture et contresigné par le Ministre des Finances déterminera les conditions d'organisation et de fonctionnement de la commission ci-dessus prévue, ainsi que les conditions d'application de la présente loi en ce qui concerne la sériciculture.

Article 3.

Quiconque aura contrevenu aux dispositions de l'article précédent ou se sera rendu coupable d'une tentative de fraude pour l'obtention de primes à la sériciculture sera passible des peines portées à l'article 471 du Code pénal.

Quiconque se sera rendu coupable d'une fraude pour l'obtention des primes à la sériciculture sera passible des peines portées aux articles 1 et 7 de la loi du 1^{er} août 1905, sans préjudice de la restitution de la prime indûment perçue.

L'article 463 du Code pénal et la loi du 26 mars 1891, sont applicables à la présente disposition.

Article 4

A partir du 1^{er} juin 1909, jusqu'au 31 mai 1929, il sera alloué aux filateurs de soie, proportionnellement au travail annuel de la bassine, une prime de quatre cents francs (400 fr.) par bassine filant à plus de trois bouts, et une prime de deux cents francs (200 fr.) par bassine même à un bout, pour les filatures de cocons doubles.

Auront droit à la prime de 400 francs les bassines accessoires servant à la préparation de la bassine fileuse

- 1 Dans les usines travaillant à plus de trois bouts et à moins de six bouts, à raison d'une bassine accessoire par trois bassines fileuses,
- 2 Dans les usines travaillant à plus de cinq bouts, à raison d'une bassine accessoire par deux bassines fileuses

En outre, dans les usines travaillant à plus de cinq bouts, il sera alloué, proportionnellement au travail annuel, une prime de quatre cents francs (400

fr) pour chaque service de noueuses ou rattacheuses desservant six bassines fileuses

Toutefois, le montant des primes, liquidées trimestriellement à chaque filateur, ne pourra excéder, par kilogramme de soie filée dans l'ensemble de ses usines, six francs cinquante centimes (6 fr 50) pendant les quatre premières années d'application de la loi, six francs (6 fr) pendant les huit années suivantes et cinq francs cinquante centimes (5 fr 50) pendant les huit dernières années d'application de la loi.

Sur le total des primes versées aux filateurs de soie, il sera prélevé six pour cent (6 pour cent) pour la constitution d'un fonds de secours et de maladie en faveur du personnel des usines, qui sera réparti par l'Etat entre les Sociétés de secours mutuels constituées par le personnel ouvrier des usines de filature

Un règlement d'administration publique déterminera la nature et la quotité des secours, la circonscription de chaque Société, leur mode d'administration, de gestion et de contrôle

Les statuts de ces Sociétés devront être approuvés par arrêtés ministériels, conformément aux dispositions du titre III de la loi du 1^{er} avril 1898, relative aux Sociétés de secours mutuels

Article 5.

Le montant de la prime fixée par l'article 4 à 400 francs par bassine à plus de trois bouts sera réduit à trois cent quarante francs (340 fr) et celui de la prime de 200 francs par bassine, même à un bout, pour les filatures de cocons doubles, sera réduit à cent soixante-dix francs (170 fr) pour les bassines filant des cocons étrangers, avec un maximum inférieur de un franc (1 fr) au maximum établi par ledit article par kilogramme de soie filée

A cet effet, il sera déduit du montant total de chaque liquidation trimestrielle de prime, calculée comme si, dans les bassines, il n'avait été filé que des cocons français, une somme de vingt-cinq centimes (0 fr 25) par kilogramme de cocons secs étrangers pris en charge dans l'ensemble des usines du filateur pendant le même trimestre

Les cocons étrangers susceptibles d'être filés ne pourront circuler, en France, qu'en vertu d'acquits-à-caution garantissant leur prise en charge dans une filature de soie ou leur réexportation

Article 6

En vue du contrôle du nombre des heures de travail et des quantités de soie filée, les filateurs devront tenir, dans chaque usine, un livre de filature dans des conditions uniformes qui seront déterminées par le règlement d'administration publique, et un registre dit de contrôle, sur lequel ils porteront, en conformité avec leur livre-journal, le poids net des cocons reçus ou revendus et le poids net des soies sorties de l'usine

Le filateur certifiera la conformité de ces extraits avec son livre-journal

Il sera constitué une Commission chargée du contrôle trimestriel des primes, et composée d'agents de l'Etat et de filateurs

Un règlement d'administration publique déterminera les conditions d'organisation et de fonctionnement de cette Commission, ainsi que les conditions d'application de la présente loi, en ce qui concerne la filature de la soie

Article 7

Les infractions aux dispositions réglementaires présentant seulement le caractère d'erreurs ou de négligences seront soumises à l'examen de la Commission de contrôle prévue à l'article précédent et pourront entraîner, pour l'usine, la suppression du droit à la prime pendant une semaine, et, en cas de récidive, pendant un mois ou un trimestre

Quiconque se sera rendu coupable d'une fraude ou d'une tentative de fraude pour l'obtention de la prime sera, à l'avenir, déchu du droit à la prime.

sans préjudice de la restitution de la prime indûment perçue et sera passible des peines portées aux articles 1 et 7 de la loi du 1^{er} août 1905

L'article 463 du Code pénal et la loi du 26 mars 1891 sont applicable à la présente disposition

Article 8

Pourront entraîner pour l'usine la suppression du droit à la prime pendant une semaine au moins et pendant un trimestre au plus, les infractions aux dispositions des lois concernant l'hygiène et la sécurité des travailleurs, qui auront fait l'objet de condamnations devenues définitives. Ladite suppression du droit à la prime sera prononcée dans la même forme que celle prévue au paragraphe premier de l'article 7 de la présente loi

Article 9

Le taux des primes ne pourra être modifié que par une loi. Un rapport sur les résultats de la présente loi sera publié au *Journal officiel* le 31 mai 1909, contenant un tableau des paiements effectués

Article 10

Les frais de surveillance et de contrôle nécessaires pour l'application de la présente loi, en ce qui concerne les primes à la filature de la soie, sont à la charge des intéressés. Le montant en est recouvré au moyen d'une retenue fixée à 1 fr 50 centimes effectuée sur le montant de chaque liquidation de primes. La somme ainsi retenue est versée au Trésor public au titre des "produits divers du budget"

Dans le cas où, par suite de modifications au chiffre des crédits votés pour les primes à la filature, la recette provenant de l'application du taux de 1 fr 50 centimes sera inférieure au montant des dépenses de surveillance et de contrôle, un nouveau taux pourra être fixé par décret rendu sur la proposition du Ministre des Finances et du Ministre du Commerce et de l'Industrie.

Article 11.

La présente loi est *applicable à l'Algérie*

La présente loi délibérée et adoptée par le Sénat et par la Chambre des députés sera exécutée comme loi de l'État.

Fait à Paris le 11 juin 1909

A FAILLIÈRES

Decret portant règlement d'administration publique pour l'application, en ce qui concerne les primes à la filature de la soie, de la loi du 11 juin 1909, relative aux encouragements spéciaux à la sériciculture et à la filature de la soie (Decret du 23 septembre 1909)

Article 1

Les primes allouées aux filateurs de soie par la loi du 11 juin 1910 sont liquidées dans les conditions déterminées ci-dessous, proportionnellement au nombre d'heures de travail accompli par les bassines et par les services de noueuses ou rattacheuses

Article 2

Sous réserve de l'application des maxima fixés par l'article 4 de la loi du 11 juin 1909, il est alloué au filateur pour chaque heure de fonctionnement d'une bassine —

0 fr 1333 pour une bassine à plus de trois bouts,

0 fr 1333 par bassine accessoire primée

0 fr 06666 par bassine même à une bout pour filature de cocons doubles Est compté comme une bout pour l'application du présent règlement, l'assemblage des baves de cocons réunies dans la première filière placée immédiatement au-dessus de la bassine

Il est, en outre, alloué au filateur 0 fr 13333 par chaque heure de fonctionnement d'un service de noueuses ou rattacheuses. Quelque soit le nombre des services de noueuses le montant des primes trimestriellement allouées pour le travail de ces services ne peut dépasser le sixième du montant des primes allouées, pendant la même période, pour le travail des bassines fileuses à plus de cinq bouts

Article 3

Pour ouvrir le droit à la prime, chaque bassine fileuse doit être menée par une ouvrière spéciale. Quelque soit le nombre des bassines accessoires servant à la préparation du travail des bassines fileuses à plus de trois bouts, le montant des primes trimestriellement allouées pour le travail de ces bassines ne peut dépasser le tiers du montant des primes allouées, pendant la même période, pour le travail des bassines fileuses à moins de six bouts ou la moitié du montant des primes allouées pour le travail des bassines fileuses à plus de cinq bouts

Pour ouvrir le droit à la prime, chaque bassine accessoire doit être menée par une ouvrière spéciale

Toutefois, lorsque les bassines accessoires sont mues mécaniquement, le nombre des ouvrières qui les mènent peut être seulement du quart du nombre des bassines accessoires

Article 4

Ne sont considérées comme bassines à plus de trois bouts, donnant droit à la prime, que les bassines chauffées à la vapeur et dont les guindres sont actionnés par un moteur mécanique

Article 5

Les filateurs conservent l'intégralité de leurs droits à la prime pour les bassines en état de filer à plus de trois bouts, alors même que ces bassines ne fileraient qu'à deux bouts ou à trois bouts, pourvu que les soies filées à deux bouts présentent 1 gramme au minimum par 450 mètres de longueur (fils gros dits du titre 20 et au-dessus), et que les soies filées à trois bouts présentent au moins 85 centigrammes par 450 mètres de longueur (fils gros dits du titre 17 et au-dessus)

Ils conservent également l'intégralité de leurs droits à la prime pour les bassines en état de filer à plus de cinq bouts, alors même que ces bassines ne fileraient qu'à cinq ou quatre bouts, pourvu que les soies filées présentent au moins 65 centigrammes par 450 mètres de longueur (fils dits du titre 13 et au-dessus).

Article 6

L'administration remettra à chaque filateur imposable comme tel à la contribution des patentes, et qui lui en fera la demande sur papier timbré, un registre nominatif trimestriel à souche pour les déclarations journalières, un livre de filature et un registre dit de contrôle à feuilles numérotées

Les modèles de ces livres et registres sont fixés par arrêté du Ministre du commerce

Les filateurs joindront à leur demande les indications suivantes sur leur outillage et sur l'organisation du travail —

- 1 Nombre des bassines fileuses à plus de trois bouts et à moins de six bouts,
- 2 Nombre des bassines fileuses à plus de cinq bouts,
- 3 Nombre des bassines accessoires en spécifiant si les opérations effectuent à la main ou mécaniquement.

- 4 Nombre des services de noueuses ou rattacheuses;
- 5 Nombre des bassines même à un bout pour filatures de cocons doubles.

Article 7.

Pour l'application du présent règlement la journée de travail est divisée en périodes ou seances Une affiche apposée en un endroit apparent de l'usine indique l'heure du commencement et la durée de chacune de ces périodes Une copie de cette affiche est adressée à l'inspecteur divisionnaire du travail et au directeur des contributions indirectes de la circonscription, qui devront être informés vingt-quatre heures à l'avance de toutes les modifications apportées à cette division de la journée de travail

Article 8

Dans la première demi-heure de l'ouverture réglementaire de chacune des périodes de travail le filateur ou son représentant inscrit sur la souche de la partie du registre de déclarations afférente à cette période et dans les blancs ménagés à cet effet —

- 1 La date du jour,
- 2 L'heure d'ouverture de chaque séance de travail et celle de sa clôture,
- 3 Le nombre d'heures de travail effectif,
- 4 Le nombre des bassines fileuses en activité le nombre des bassines mues mécaniquement et le nombre des services de noueuses ou rattacheuses en activité,
- 5 Le titre filé par des bassines filant à deux, trois, quatre ou cinq bouts dans le cas prévu par l'article 5

Le nombre des bassines mises en œuvre et celui des services de noueuses ou rattacheuses sont inscrits en toutes lettres

Cette déclaration est signée et ne doit contenir ni rature ni surcharge.

Elle est reproduite sur le volant suivant les dispositions prescrites par arrêté du ministre du commerce

Une demi-heure après l'ouverture de chaque séance, le volant séparé de la souche doit être déposé dans une boîte placée à l'entrée de l'usine et scellée au mur

Cette boîte dont le modèle est fixé par l'Administration, est fermée par deux serrures

La clef de l'une de ces serrures reste entre les mains de l'industriel La clef de l'autre serrure est confiée à un agent de l'administration

Article 9.

En cas de chômage accidentel de l'usine pendant un jour ou une fraction de journée, la mention " chômage pour la séance " ou " pour la journée " doit être inscrite au plus tard à l'heure réglementaire sur la souche et le volant de chaque déclaration ordinaire. Le volant est déposé dans la boîte

En cas de chômage prolongée de l'usine, le filateur peut s'affranchir de l'obligation de signer chaque jour pour les déclarations de chômage en renvoyant le registre au ministère du commerce

Article 10.

Si par suite d'une circonstance fortuite, une ou plusieurs ouvrières quittent l'usine pendant une période réglementaire de travail sans être remplacées par d'autres ouvrières la première déclaration est rectifiée par l'inscription immédiate sur le registre, dans la colonne des observations, de

l'heure du départ des ouvrières et de leur nom, ainsi que du nombre et de la nature des bassines qui viendraient à être mises ainsi en chômage

Un bulletin de correction est, en même temps, déposé dans la boîte

Article 11

Les filateurs possédant plusieurs usines doivent, pour chacune de ces usines, tenir un livre de filature et un registre de contrôle

Article 12

Le livre de filature indique l'organisation et le développement du travail dans l'usine

A cet effet, le filateur mentionne en tête du livre trimestriel et par chaque atelier —

- 1 Le numéro de chaque bassine fileuse, en indiquant le nombre des bouts qu'elle est en état de filer,
- 2 Le numéro de chaque bassine accessoire, en spécifiant si elle est mue à la main ou mécaniquement et en indiquant les numéros des bassines qu'elle dessert,
- 3 Le numéro de chaque service de noueuses en indiquant les numéros des bassines qu'il dessert

En outre, le filateur inscrit jour par jour sur le livre —

- 1 Les noms des ouvrières concourant directement à la production de la soie par catégorie (fileuses à moins de six bouts, fileuses à plus de cinq bouts, batteuses, noueuses ou rattacheuses et leurs remplaçantes) et les numéros des bassines auxquelles elles sont affectées,
- 2 Le nombre d'heures de fonctionnement de chaque bassine et de chaque service,
- 3 Les pesées de soie qui auraient été successivement effectuées par bassine à chaque tombée de guindre en indiquant le titre de la soie filée

A la fin de chaque semaine, ces chiffres partiels sont totalisés de manière à présenter —

- 1 Le total des heures de fonctionnement de chaque bassine ou service, et le nombre total des heures de fonctionnement dans chaque catégorie,
- 2 Le total des pesées successives de soie et le total général de la soie produite pendant la semaine

Les colonnes d'heures de travail et de pesées des soies ne doivent contenir aucun blanc. Le filateur doit donc, soit inscrire à chacune des colonnes un chiffre d'heures ou un poids de soie, soit y tracer une croix épaisse s'opposant à toute inscription ultérieure

A la fin du trimestre, les chiffres des heures de fonctionnement des bassines ou des services par catégorie et des pesées de soie de chaque semaine sont totalisés

Les flottes de soie correspondant à la dernière pesée inscrite sur le livre de filature doivent être conservées avec le numéro de l'ouvrière dans le magasin de la filature à la disposition des agents de l'Administration jusqu'à la pesée suivante, sans que toutefois ce délai puisse excéder vingt heures, à partir de la fin de la journée, non compris les dimanches et jours fériés

Ces agents peuvent faire procéder en leur présence, par le personnel de l'usine, au pesage des flottes de la dernière pesée pour s'assurer que leur poids correspond à celui qui est inscrit dans la colonne des pesées. Ils peuvent

également, en cas de présomption d'erreur importante, se faire représenter la soie en magasin et faire procéder au pesage de cette soie en leur présence par le personnel de l'usine

Un extrait certifié conforme du livre de filature, indiquant pour chaque semaine la liste nominative de toutes les ouvrières, la nature de leur emploi et le nombre d'heures de travail effectué par chacune d'elles, restera, pendant la semaine suivante et à partir du mercredi matin au plus tard, affiché dans une partie bien en vue de l'atelier

Article 13

Le registre de contrôle indique la situation de l'usine au point de vue des entrées et des sorties des marchandises

Sur la première feuille de ce registre, le filateur inscrit le poids net du stock des cocons et des soies existant dans le magasin de la filature au premier jour du trimestre

Sont successivement inscrites à leurs dates dans chacune des colonnes du registre réservées à cet effet —

- 1 Les entrées ou sorties de cocons frais ou secs d'origine française et de cocons secs d'origine étrangère,
- 2 Les sorties de soie filée

En cas d'envoi de cocons étrangers déjà pris en charge par une filature à une autre filature, l'entrée doit être portée dans la colonne réservée aux cocons étrangers, mais en indiquant comme observation qu'ils ont été antérieurement nationalisés. Le registre mentionne également (1) dans la filature qui reçoit les cocons, le nom et le lieu de la filature qui les envoie et, s'il est possible, la date et le numéro de l'acquit-à-caution en vertu duquel ils ont été autorisés à circuler en France, (2) dans la filature qui les envoie, le nom et le lieu de la filature à laquelle ils sont destinés

Dans les usines comprenant à la fois des ateliers de filature et des ateliers de moulinage, les soies filées entrées au moulinage doivent être inscrites comme sorties de la filature à leur d'entrée dans l'atelier de moulinage

A la fin de chaque semaine, le filateur relève, en outre, dans les colonnes réservées à cet effet le poids net des cocons filés et le poids de la soie obtenue pendant la semaine. Si le filateur exploite à la fois des bassines servant à la filature des cocons simples et des bassines servant à la filature des cocons doubles, le poids de la soie provenant de la filature des cocons simples et le poids de la soie provenant de la filature des cocons doubles sont inscrits dans deux colonnes distinctes.

A la fin du trimestre, le filateur fait ressortir sur le registre de contrôle la quantité de soie française et étrangère filée pendant le trimestre

L'application des maxima fixés par l'article 4 de la loi du 11 juin 1909 sera faite séparément à ces deux catégories de soie

A la fin du trimestre, le filateur inscrit le stock des cocons et des soies en magasin et clôt le registre de contrôle par la mention suivante "Certifié en conformité des écritures qui sont énoncées au livre-journal, réserves étant faite, en ce qui concerne les soies, de la tolérance d'un écart de poids de 5 p 100 correspondant, soit à la perte en condition, soit au déchet de moulinage

Article 14

Les agents chargés d'assurer l'exécution des dispositions de la loi du 11 juin 1909 et du présent règlement, relatives aux primes à la filature, sont désignés par le ministre du commerce et de l'industrie et choisis parmi les agents de l'Administration des douanes et des contributions indirectes, les inspecteurs du travail et les vérificateurs des poids et mesures. Ces agents ont le droit d'entrer à toute heure de la journée dans les filatures de soie ayant réclamé le bénéfice des primes et dans les locaux annexes servant de

magasin pour les cocons et les soies filées Ils peuvent exiger la communication sur place des livres de journée et de paye de l'établissement ainsi que des livres d'achat des cocons, et de sortie des soies filées Ils peuvent également prélever des échantillons des titres filés dans les conditions de l'article 15 et faire établir les titres par le personnel de l'usine

Article 15

A chacune de leurs visites, les agents de l'Administration s'assurent de l'observation des prescriptions du règlement, vérifient l'exactitude des diverses déclarations imposées au filateur et apposent leur signature sur le registre de déclarations, sur le livre de filature et sur le registre dit "de contrôle".

S'ils constatent une irrégularité, ils en rendent compte dans un rapport qui est transmis par la voie hiérarchique au ministre du commerce et au ministre des finances S'ils constatent une fraude ou tentative de fraude, ils dressent un procès-verbal qui est transmis au parquet

Un agent de l'Administration est spécialement chargé pour chaque usine, de garder la clef de l'une des serrures de la boîte prévue à l'article 8

A chacune de ces visites, cet agent ouvre la boîte en présence du filateur ou de son fondé de pouvoir, il en retire tous les volants qui y ont été déposés depuis sa dernière visite

Après avoir classé ces bulletins par date, il les compare à la souche du registre et, s'il constate la conformité des écritures et du nombre, il donne au filateur décharge des volants dans la colonne d'observations de la souche portant la date de sa visite

En cas de divergence du volant avec la souche ou de manquants, l'agent mentionne les irrégularités sur chacune des souches qu'elles concernent et en fait l'objet d'un rapport ou d'un procès-verbal

Les volants, réunis en liasse et accompagnés d'un bordereau qui mentionne leur nombre, sont envoyés sous pli recommandé au ministère du commerce

Le registre des déclarations journalières n'est envoyé par le filateur au ministère du commerce qu'après que l'agent de l'Administration a vérifié et extrait de la boîte tous les volants afférents au trimestre écoulé

Article 16

Les primes à la filature sont liquidées par trimestre Les filateurs adressent directement, pli recommandé, au ministre du commerce et de l'industrie, les pièces constatant le droit à la prime, savoir —

- 1 Un bulletin trimestriel récapitulatif faisant ressortir le total des primes réclamées pour chaque espèce de bassine et pour chaque service de noueuses ou rattacheuses, calculées conformément aux prescriptions de l'article 4, et le poids de la soie filée dans l'usine avec l'indication du poids de la soie provenant de la filature des cocons doubles Le filateur conserve comme titre la souche de ce bulletin,
- 2 Un extrait du rôle des patentes pour l'année courante, et, en cas de mise en activité, en cours d'année, de nouvelles bassines, soit l'extrait du rôle supplémentaire des patentes, soit au moins un certificat du service des contributions directes, constatant que la déclaration en a été faite en temps utile,
- 3 Le registre des déclarations journalières,
- 4 Le livre de filature,
- 5 Le registre dit de contrôle

Ces trois registres doivent avoir conservé le nombre exact de feuilles numérotées qu'ils contenaient lors de leur remise par l'Administration En cas de non-représentation, même d'une seule de ces feuilles il n'est pas procédé à la liquidation

Ces pièces sont vérifiées par le service compétent qui propose au ministre l'approbation des états collectifs de dépense

Dans les cas prévus par les articles 7, S I et 8 de la loi du 11 juin 1909, le ministre ne prend pas de décision définitive qu'après avis de la Commission de contrôle.

Un extrait de l'état des dépenses approuvées est transmis au préfet du département avec les pièces comptables

Le Ministre du commerce et de l'industrie adresse en même temps à chaque préfet une ordonnance de délégation en vertu de laquelle des mandats sont délivrés individuellement à chacun des filateurs.

Article 17

La Commission de contrôle instituée par l'article 6 de la loi est nommée par arrêté du Ministre du commerce et de l'industrie et composée suit

Membres de droit

Le Directeur Général des Douanes ou son délégué

Le Directeur Général des Contributions indirectes ou son délégué

Le directeur des affaires commerciales et industrielles au Ministère du Commerce et de l'industrie ou son délégué

Le directeur dans les attributions duquel rentre le service de la comptabilité du Ministre du commerce et de l'industrie ou son délégué

Membres nommés

Deux membres de Conseil d'Etat, dont un conseiller d'Etat président de la Commission,

Un inspecteur des finances

Un inspecteur du travail

Cinq filateurs de soie ou anciens filateurs et cinq suppléants

Deux auditeurs au Conseil d'Etat sont adjoints à la Commission comme rapporteurs

Un secrétaire et un secrétaire adjoint sont choisis parmi les chefs et sous-chefs de bureau du Ministère du commerce et de l'industrie

Les membres ne faisant pas partie de droit de la Commission sont nommés pour trois ans et peuvent être renommés

La Commission se réunit tous les trois mois sur la convocation du Ministre du commerce Sur le rapport qui lui est présenté par les secrétaires et les rapporteurs, elle donne son avis sur la liquidation des primes réclamées par les filateurs, ainsi que sur les cas litigieux qui lui sont signalés par l'Administration

Article 18.

Les cocons étrangers susceptibles d'être filés sont admis en entrepôt fictif dans les ports où cet entrepôt est autorisé, moyennant une soumission cautionnée d'en représenter les poids nets en mêmes quantités et qualités, sous les mêmes marques et numéros, à toute réquisition, ou de payer une somme de 50 centimes par kilogramme manquant.

Il sera toutefois admis un déchet de 10 p 100, tant pour défaut de siccité lors des pesées que pour prélèvement d'échantillons

Les cocons ne pourront être changés de magasin sans une déclaration préalable et un permis spécial de la douane

Ils ne pourront sortir de l'entrepôt pour l'intérieur que sous le couvert d'un acquit-à-caution portant engagement de rapporter dans un délai de trois

mois le certificat émanant soit du service des Douanes, soit de celui des contributions indirectes ou diverses constatant, soit la prise en charge dans une filature, soit la réexportation, ou de payer une somme de 50 centimes par kilogramme non apuré

Le délai fixé pour la décharge de l'acquit-à-caution peut être sur la demande motivée du soumissionnaire, prolongé d'une durée qui ne peut excéder trois mois par décision du Ministre des finances, sur avis conforme du Ministre du commerce.

Dans les villes où l'entrepôt fictif n'est pas autorisé, les cocons pourront être placés en entrepôt réel aux frais des destinataires jusqu'à la levée des acquits-à-caution applicables à leur transport en filature ou à leur réexportation

Dans le cas d'envoi au filature l'acquit-à-caution est déchargé sur le vu du certificat de prise en charge du filateur ou de son fondé de pouvoirs, dûment autorisé par le service des Douanes ou des contributions indirectes

Dans le cas de réexportation l'acquit-à-caution est déchargé sur le vu du certificat du bureau de douane de sortie

Après décharge de l'acquit-à-caution constatant la prise en charge dans une filature il en est envoyé un double au Ministre du commerce en vue de la liquidation des primes dues au filateur qui les a pris en charge

L'entrée et le transport des échantillons de cocons d'un poids de 4 kilogrammes et au-dessous ne sont soumis à aucune formalité

Article 19

Le présent décret est applicable à l'Algérie

Article 20

Le Ministre du commerce et de l'industrie et le Ministre des finances sont chargés, chacun en ce qui le concerne, de l'exécution du présent décret, qui sera publié au Journal Officiel et inséré au Bulletin des Lois

Fait à Rambouillet, le 23 septembre 1909
